4. Position water by-pass pipe on water pump on left bank thermostat housing cover. Secure to water pump with hose connection and clamp to cover with capscrews, flatwashers and lockwashers.
5. Position and secure cross-over pipe and gaskets between thermostat housing covers.
6. Position and secure hoses on each thermostat outlet connection.
7. Fill cooling system, start engine and check for leaks.

WATER PUMP

C and J Naturally Aspirated

1. Loosen clamp and disconnect hose at water pump inlet connection.
2. Remove water pump belt.
3. Unfasten pump from gear housing.
4. Remove pump from engine by separating from water by-pass coupling and oil cooler connection.

Installation

1. Install new rubber O-rings on oil cooler connection and water by-pass coupling.
2. Lift pump into position and secure to gear housing.
3. Adjust belt tension.

C and J Supercharged

1. Disconnect hose at water pump inlet connection.
2. Remove oil cooler.
3. Unfasten pump from supercharger.
4. Disconnect pump from water by-pass coupling and remove from engine.
5. Remove capscrew holding oil cooler connection to pump and remove connection.

Installation

1. Assemble new rubber O-ring on oil cooler connection and attach connection to water pump.
2. Install new rubber O-ring on water by-pass coupling.
3. Attach pump to coupling and supercharger, using new gasket.
4. Install oil cooler.

H, NH and NT Engines

1. Remove fan from pulley.
2. Loosen adjusting screw and remove fan hub, pulley and belts.
3. If used, remove bell crank arrangement from rocker housing and compression release lever.
4. Loosen and remove capscrews holding fan bracket support to rocker housing. *The fan bracket on many engines is also a clamp ring to secure water pump. Loosen capscrews in clamp ring.*
5. Using a screwdriver in holes provided in water pump housing, turn water pump to lowest point of its eccentric to loosen water pump belt.
6. Remove pump belt, fan bracket and support.
7. Remove water pump from engine.

Installation

1. Place clamp ring and gasket on water pump.
2. Assemble drive belt on pump pulley and pump drive pulley.
3. Turn pump to low point of its eccentric and install in place. Secure lightly with capscrews and lockwashers.
4. Insert large screwdriver in holes provided in water pump. Turn water pump on its eccentric counter-clockwise to tighten belt.
5. Tighten capscrews in clamp ring.
6. Secure fan bracket support to rocker housing with capscrews and lockwashers.
7. Assemble belts over fan pulley and fan drive pulley.
8. Assemble fan pulley to water pump bracket. Avoid stretching belts; loosen adjusting screw until belts go into position easily.
9. Tighten adjusting screw to get proper tension on drive belts and tighten hub to bracket. Pack fan hub bearings with ball bearing grease.
10. Assemble fan and dirt exclusion plate to fan hub.

V6-200, V8-265 Engines

1. Remove fan from fan pulley.
2. Loosen generator adjusting link and remove generator drive belt.
3. With high mount fan, loosen fan drive adjusting screw and remove fan and pump drive belts.
4. Drain cooling system.
5. Remove lower hose from pump and loosen clamps on upper hose.
6. Remove all accessory lines from pump body.
7. Unfasten pump from block. Rotate pump housing to clear upper hose connection and lift out pump.

Installation

1. With new gasket, insert pump in block. Rotate pump to install upper hose and hose clamps. Secure pump in position.
2. Connect lower hose to pump.
3. With high mount fan, place fan and pump drive belts on pulley and draw to proper tension with fan drive adjusting screws.
4. Position generator belt on pulleys. Lift generator to obtain proper belt tension and secure with adjusting link and capscrew.
5. Install fan on pulley.
6. Connect accessory lines to pump. Close all drainage points, fill cooling system, start engine and check for leaks.

V8-350, VT8-430 Engines

1. Drain cooling system.
2. Remove capscrews securing pulley sheave to drive pulley. Unscrew sheave from pump shaft by turning counter-clockwise. Remove drive belt.
3. Disconnect all water hose connections.
4. Disconnect corrosion resistor hose from pump.
5. Unfasten and lift pump from block.

Installation

1. Install pump to block with new gasket.
2. Connect corrosion resistor hose to tee connection on pump.
3. Install all hose connections.
4. Place drive belt on water pump shaft and screw on pulley sheave. It may be necessary to turn engine with a bar to achieve proper belt tension. Secure sheave with capscrews and lockwashers.
5. Fill cooling system, start engine and check for leaks.

TURBOCHARGER

Service Note

All production model Cummins turbochargers are oil cooled. Removal and instructions given below apply only to the oil-cooled type.

Cummins turbochargers can be mounted in several positions. Although disassembly and rebuild procedures may vary slightly with each installation, the following precautions must be taken with all turbochargers.

1. Lubricating oil drain (large boss) must be down or within 45° of that position, Fig. 1
2. Never carry the weight of the exhaust piping on the turbocharger.
3. When turbocharger is dismounted, always cover inlet and outlet ports to prevent entrance of dirt.
4. Never stuff rags into ports.
5. Never use a caustic solution to clean any part of turbocharger.
6. Never use a wire brush to clean com-

pressor wheel, turbine or diffuser plate.
7. Never attempt to disassemble, repair or alter a turbocharger in any way. Your Cummins dealer is equipped with the proper tools to rebuild Cummins turbochargers.

J and C Engines

1. Remove oil lines connecting turbocharger to oil cooler and oil pan.
2. Disconnect hose from turbocharger to intake manifold.
3. Loosen and remove capscrews and lift off turbocharger.

Installation

1. Install gasket and lift turbocharger into position against exhaust manifold and secure.
2. Secure bracket between turbocharger and oil cooler (rear mount fastens to clutch housing).
3. Install oil flow regulator valve in oil cooler (if used). With rear mount units, the regulator is installed in an elbow in the oil transfer connection.
4. Install oil supply line between regulator valve and turbocharger.
5. Connect turbocharger oil drain line (large) to crankcase.
6. Assemble and tighten air inlet and outlet piping to turbocharger.

H, NH, NT Engines

1. Disconnect oil lines.
2. Loosen intake and discharge air connections.
3. Unfasten and remove turbocharger from its mounting bracket and exhaust manifold.

Installation

1. Install gasket and turbocharger to exhaust manifold.
2. Secure mounting bracket to turbocharger casing.
3. Connect oil inlet line from top of turbocharger to oil cooler or rear of block.
4. Connect oil drain line from large boss on side of turbocharger to crankcase.
5. Install hose from blower outlet to intake manifold connection.
6. Install air cleaner and exhaust piping.

V8-350, VT8-430 Engines

1. Remove glow plug electrical leads and fuel lines to preheater nozzles from both air intake connections between rocker cover and turbocharger.
2. Remove aneroid control air line from left bank intake manifold connection.
3. Remove capscrews securing connections to rocker covers. Rotate and remove air connections from both banks. Discard O-rings.
4. Disconnect connection between air cleaner and turbocharger at turbocharger air intake.
5. Remove connection from exhaust outlet of turbocharger.
6. Remove V-type clamp rings attaching exhaust manifolds to turbocharger exhaust intakes.
7. Unfasten and remove turbocharger from accessory support cover.

Fig. 1 Oil drain position for turbocharger

Installation

1. Secure turbocharger with new gasket to accessory support cover. *Make sure oil supply and drain holes to turbocharger are open.*
2. Connect exhaust manifolds to turbocharger exhaust inlets and secure V-type clamp rings.
3. Install connection on turbocharger exhaust outlet.
4. Install connection from air cleaner to turbocharger air intake.
5. Install new O-rings on air crossover.
6. Insert air outlet connection in turbocharger and secure to each rocker cover with capscrews.
7. Connect fuel lines to preheater nozzles in each air intake connection.
8. Connect electrical leads to each glow plug.
9. Connect aneroid control air line.

SUPERCHARGER

In Line Engines

1. Remove capscrews which secure air connection to intake manifold. Using a screwdriver, pry springs from supercharger connection at the outlet. Cover connection opening in supercharger to prevent entrance of dirt.
2. Remove heat shield and supercharger outlet.
3. Remove oil filler tube and cover plate from cylinder block.
4. Disconnect and remove lubricating oil supply and drain lines from supercharger and hand hole covers.
5. While supporting supercharger, remove capscrews from supercharger and engine.
6. Disengage supercharger coupling from drive unit and lift off engine. *NHHS superchargers are flange mounted to gear case and cover.*

Installation

1. Keep ports covered at all times before final assembly of inlet and outlet ends of manifold to supercharger. Masking tape may be used.
2. Assemble inlet and outlet connections to supercharger. Use hug-nuts and flatwashers to secure connections in place.
3. Lift supercharger to engine and engage coupling to drive unit.
4. Start upper left and lower right bolts to support supercharger.
5. Start and tighten upper right and lower left support bolts. The corresponding bolt holes in the supercharger are reamed to fit support bolts snugly.
6. Tighten remaining support bolts. *Do not overtighten as the housing may be distorted causing the rotors to scrape.*
7. Place rubber buffer in generator drive coupling and mount generator.
8. Install lubricating oil supply and drain lines to supercharger and hand hole covers.

OIL COOLER

Service Note

When cleaning the cooler, do not use solvent that is harmful to copper. Do not use mechanical cleaning methods such as scraping. Finish cleaning by blowing through bundle with compressed air. Clean the housing with solvent and compressed air.

C and J Engines

1. Disconnect oil and water lines and electric units from oil cooler.
2. Unfasten and remove cooler from engine.
3. Remove front cover.
4. Discard gaskets and O-rings.
5. Insert two $\frac{5}{16}$" capscrews in tapped holes at end of cooler element. Pull element with capscrews.

Installation

1. Lubricate O-ring and insert in bottom of housing.
2. Install element, aligning "O" marks on housing and element.
3. Place new front cover O-ring and gasket on housing.
4. Install front cover and secure with capscrews.
5. Place new gaskets on block, position oil cooler on block and secure with lockwashers and capscrews. Use new gaskets and O-rings on water pump connection.
6. Connect water and oil lines removed from cooler.

H, NH, NT Engines with Non Oil-Cooled Pistons

1. Disconnect water inlet and by-pass connection from oil cooler and cylinder heads.
2. Remove external oil inlet and drain lines (if used).
3. Unfasten and remove cooler from cylinder block.
4. Remove steel retainer ring.
5. Insert capscrews in tapped holes provided in element and pull element from housing.

H, NH, NT Oil-Cooled Piston Engines

1. Repeat Steps 1 and 2 above.
2. Unfasten and remove cooler from support.
3. Remove steel retainer ring.
4. Unfasten and remove cooler support from block.

Installation

1. Lubricate new O-ring and install at bottom of oil cooler housing.
2. Push element into housing, aligning "O" index marks. Remove capscrews used for insertion.
3. Install new O-ring on top of element.
4. Place steel retainer over O-ring. Install new gasket over steel retainer.
5. On oil cooled piston engines only, install new gasket to block. Install oil cooler support to block.
6. Install oil cooler.
7. Install external oil inlet and drain lines (if used).
8. Connect water inlet and by-pass connections from cylinder head to cooler.

V8-350, VT8-430 Engines

1. Drain cooling system.
2. Remove hoses and clamps from water inlet and outlet connections.
3. Unfasten and remove oil cooler from engine.
4. Remove connections from cooler.

Installation

1. Place new gaskets at each end of bundle and install connections.
2. Install bundle and connections to engine.
3. Install inlet and outlet hose.
4. Fill cooling system, start engine and check for leaks.

FUEL PUMP

C, J, H, NH, NT Engines

The fuel pump is flange-mounted to the accessory drive on the gear housing or to the rear of the air compressor.

1. Remove fuel line connecting fuel pump and inlet manifold.
2. Disconnect fuel pump inlet and drain lines.
3. If engine is equipped with aneroid control, disconnect two lines from aneroid to fuel pump.
4. Disconnect throttle linkage.
5. Unfasten and remove fuel pump from engine. Remove rubber coupling from drive unit.

Installation

1. Install new gasket, rubber buffer and fuel pump.
2. Connect pump drain and inlet lines.
3. Install fuel line from pump to fuel inlet manifold.
4. Connect throttle linkage to pump.

V6-200, V8-265 Engines

1. Loosen hose clamps securing air intake hose connections to air crossover pipe.
2. Disconnect air compressor intake line from air intake crossover pipe.
3. Disconnect preheater electrical leads and fuel lines.
4. Unfasten and lift off air crossover pipe from valve covers.
5. Remove fuel supply line from fuel pump shut-down valve to fuel supply crossover.
6. Remove fuel inlet line at fuel pump gear pump.
7. Disconnect electric wire from fuel shut-down valve.
8. Disconnect throttle linkage.
9. Unfasten and remove fuel pump from accessory drive housing or air compressor.

Installation

1. Install fuel pump with new gasket and coupling in position.
2. Connect throttle linkage.
3. Connect electrical wire to fuel shut-down valve.
4. Connect fuel inlet line to fuel pump gear pump.
5. Connect fuel supply line to fuel pump shut-down valve.
6. Install air intake crossover pipe and new gasket to valve covers.
7. Connect air compressor air intake line to air crossover pipe.
8. Connect preheater electrical leads and fuel lines.
9. Secure air intake hose to air crossover pipe.
10. Start engine and check for leaks.

V8-350, VT8-430 Engines

The fuel pump is mounted to the accessory support cover and is driven through a spider coupling. The feet supporting the fuel pump are dowelled in place by two ring dowels. Alignment with the drive coupling is made by adjusting shims between the fuel pump mounting pads and the feet.

1. Remove generator adjusting link capscrew. Lower generator and remove belt. Rotate generator outward to clear fuel pump.
2. On turbocharged engines, disconnect fuel oil by-pass line to aneroid control. Disconnect fuel oil suction line at gear pump, and fuel supply tube at fuel shut-down valve.
3. Disconnect throttle linkage.
4. Unfasten and lift off fuel pump. *Do not lose adjusting shims.*

Installation

1. If a new or exchanged pump is being installed, make certain the rubber coupling buffer work freely with a minimum of $\frac{1}{16}$ inch end clearance to prevent binding during operation.
2. Unfasten and remove pulley spider to accessory drive pulley. Remove shims.
3. Mount fuel pump on accessory cover support.
4. Attach dial indicator to accessory drive pulley; place dial arms on pump spider.
5. Turn engine with a bar and make indicator readings at four equidistant points on pump spider. Note reading and select shims to be installed between spider and accessory drive pulley as necessary to bring alignment with .010".
6. Remove pump and dial indicator. Replace pulley spider, using shims selected in Step 5.
7. Position fuel pump on mounting pads. Insert shims under pump mounting feet as needed for alignment. Secure pump with capscrews.
8. Connect throttle linkage, all fuel lines and tubing.
9. Rotate generator inward to position drive belt on pulley. Secure to proper belt tension with adjusting link and capscrews.

ANEROID CONTROL

In Line Engines

1. Disconnect flexible line from aneroid to fuel pump on pressure side of gear pump.
2. Remove flexible line from aneroid to fuel pump at inlet side of gear pump.
3. Remove air vent line (if used).
4. Remove air pressure hose.
5. Remove aneroid and bracket.

Installation

1. Mount aneroid and bracket as a unit as near fuel pump as possible.
2. Install fuel pressure line from gear pump to "In" connection on aneroid control.
3. Install return line from "Out" connection on aneroid control to "T" connection at suction side of gear pump.
4. Install line from top of aneroid to air intake manifold. *Use No. 5 size flexible hose between aneroid and fuel pump and No. 4 size between aneroid and air intake manifold.*
5. Install vent line (if used). *Current aneroids are equipped with air filters in place of air vent line.*

V8-350, VT8-430 Turbocharged Engines

1. Remove air pressure line from top of aneroid control.
2. Remove fuel oil line from side of aneroid control. *Cover all fuel and air openings with tape.*
3. Unfasten and remove aneroid and mounting bracket from end of air compressor.
4. Separate aneroid from bracket.

Installation

1. Secure bracket to aneroid control.
2. Mount aneroid and bracket to air compressor.
3. Remove tape from openings. Connect air pressure line to top and fuel oil line to side of aneroid control.

AIR COMPRESSOR

In Line Engines With Cummins Unit

1. Remove capscrew securing accessory drive pulley to compressor crankshaft.
2. Using puller, remove pulley from crankshaft. *Replace capscrew in end of crankshaft to prevent damage to threads.*
3. Remove pulley key.
4. On internal oil line engines only, remove oil slinger from crankshaft before proceeding.
5. Remove fuel pump.
6. Disconnect all air, water and oil lines from compressor.
7. Unfasten and remove compressor from engine. *Do not lose coupling retainer plate and rubber buffer from fuel pump end of crankshaft.*

Installation

1. Install compressor to gear case, using new gasket. *Timing marks on camshaft gear and compressor drive gear must be indexed.*

Fig. 2 Removing fuel drain connection

2. Connect air, water and oil lines to compressor.
3. If removed, install coupling retainer plate and rubber buffer on fuel pump end of crankshaft.
4. Install fuel pump, using new gasket.
5. On internal oil line engines, slide oil slinger on crankshaft.
6. Install accessory drive pulley key in crankshaft.
7. Remove large capscrew from end of crankshaft. Install pulley on crankshaft and secure with capscrews.

In Line Engines with Bendix-Westinghouse Unit

1. Remove fuel pump.
2. Disconnect oil inlet line from air compressor drive and fuel pump flange.
3. Remove oil drain tube from bottom of compressor. Disconnect water inlet and outlet tubes, and air outlet tubing from compressor.
4. Unfasten and remove compressor and splined coupling.

Installation

1. Assemble splined coupling to compressor. Assemble air compressor to accessory drive, using new gasket. Install and tighten capscrews.
2. Attach compressor support to block.
3. Connect all water, air and oil lines, or tubing.
4. Install fuel pump.

J-4 Engines

1. Disconnect oil supply line.
2. Unfasten compressor from bracket and slide compressor to disengage belt.
3. Lift compressor from bracket. Remove and discard gasket if damaged.

Installation

1. Assemble gasket on bracket and mount compressor on bracket.
2. Assemble mounting bolts. Tighten bolts when adjusting belt.
3. Connect oil supply line.

V6-200, V8-265 Engines

1. Drain cooling system.
2. Remove air intake tube from air crossover pipe and air compressor.
3. Remove fuel pump.
4. Remove water intake and outlet tube from air compressor.
5. Disconnect air compressor air pressure line.
6. Unfasten and remove air compressor.

Installation

1. Position new gasket on air compressor mounting flange. Slide compressor in gear housing, making sure gears mesh properly.
2. Position accessory drive cover plate with new gaskets to gear housing.
3. Secure cover plate and compressor with capscrews.
4. Connect water inlet and outlet tubes to compressor.
5. Install fuel pump.
6. Connect all compressor air inlet and outlet lines.
7. Fill cooling system. Start engine and check for leaks.

V8-350, VT8-430 Engines

The complete air compressor, including the drive, cannot be removed while the engine is in the chassis. However, removal of the crankcase assembly (the compressor unit most often exchanged) is easily accomplished.

1. Remove turbocharger intake connection.
2. Drain cooling system.
3. Remove lubricating oil filter. *Cover turbocharger intake opening and oil filter connections in accessory support cover with masking tape to prevent entrance of dirt.*
4. Remove aneroid control.
5. Disconnect all air and water lines from compressor.
6. Unfasten and remove air compressor cover and bracket with aneroid attached.
7. Remove capscrew, lockplate and spacer securing counterweight to compressor crankshaft.
8. Separate lockplate and spacer from capscrew and reinstall capscrew a few threads. This will provide a support for the forcing screw on a counterweight puller.
9. Position counterweight puller against compressor crankcase and secure by installing two $\frac{5}{16}$" capscrews at least 3 inches long through puller and into tapped holes in counterweight. Pull to remove weights and key from housing.
10. Remove capscrews securing crankcase to support. Slide off crankcase and connecting rod assembly from support and crankshaft.

Installation

1. Turn engine with a bar to a position that will allow the compressor rod to match the compressor crankshaft throw. *This usually is bottom center.*
2. Slide compressor crankcase over crankshaft to support. Secure with capscrews. *Care should be taken during assembly not to damage rod bearing.*
3. Install counterweight over key and crankshaft (counterweight is a light, close fit). Secure in position with spacer, lockplate and capscrew. Bend lockplate over capscrew.
4. Position air compressor cover with new gasket and aneroid mounting bracket to compressor and secure with capscrews.
5. Connect all air lines and water tubes to compressor.

Fig. 3 Installing injector

6. Install lubricating oil filter.
7. Install turbocharger intake connections.
8. Install aneroid control valve.
9. Fill cooling system and check for leaks.

INJECTORS

In Line Engines

1. Unfasten and remove rocker cover from rocker housing.
2. Remove fuel inlet and drain lines to injector connections.
3. Remove fuel inlet and drain connections from injector body. Fig. 2.
4. Loosen injector locknut and unscrew adjusting screw until push tube can be disengaged.
5. Disengage push tube and tip rocker lever back until injector can be removed. Remove hold-down capscrews and lift injector from cylinder head, Fig. 3. *Do not bruise injector tip. Do not turn injector upside down as plunger can fall out and be ruined.*

Installation

1. Wrap a clean cloth around wooden stick and clean the copper injector sleeve. *Never use a screwdriver or any metal object for cleaning sleeve.*
2. Install same type injectors as removed. Place injector in its proper position in cylinder head, being careful not to damage injector tip.
3. Start, *but do not tighten,* injector hold-down capscrews.
4. In order to align injectors before tightening hold-down capscrews, screw in inlet and drain connections about three turns.
5. Oil injector hold-down capscrews and tighten to the torque value listed in the specifications table. *Excessive tightening will distort valve seats and crack cylinder head.*
6. Tighten inlet and drain connections to 20/25 ft. lbs.
7. Assemble injector rocker lever to injector push tube.
8. Adjust injectors and valves as outlined in the *Adjustment Section* of this chapter.
9. Install rocker lever cover.

V6-200, V8-265 Engines

1. Loosen hose clamps securing air in-

take hose connections to air crossover pipe.
2. Disconnect air compressor intake line from air intake crossover pipe.
3. Disconnect preheater electrical leads and fuel lines.
4. Remove air crossover pipe from valve covers.
5. Remove valve cover.
6. Back off injector adjusting screw until clear of push rod. Push injector rocker lever down and slide push rod to one side, then tilt lever back to clear injector link.
7. Remove injector hold-down clamp.
8. Pry injector from cylinder head. Remove O-rings and discard.

Installation

1. Make certain injector is clean and that cup is tightened properly. Filtering screen must be in place with no gaps or holes.
2. Make certain copper sleeve in cylinder head is free of chips and carbon particles.
3. Install new O-rings in injector body.
4. Lubricate O-rings with Lubriplate. Do not use lubricating or fuel oil.
5. Start injector into bore, guiding it by hand until injector is aligned in bore and not binding in any manner.
6. Place hammer handle butt on injector body and seat injector by giving it a quick, hard push on the hammer. A "snap" should be heard and felt as the cup seats in the copper sleeve.
7. Install hold-down clamp and capscrew; tighten capscrew to 12/15 ft. lbs.
8. Depress injector plunger with screwdriver by pushing down on plunger top and slip injector rocker lever in place. *The plunger link and cup on rocker lever must be engaged, and the rocker lever adjusting screw must seat into the push rod socket properly or the injector cannot be adjusted correctly.*
9. Adjust injectors as outlined in the *Adjustment Section* of this chapter.
10. Install valve covers with new gaskets.
11. Install air intake crossover pipe.
12. Connect air compressor air line to air crossover pipe.
13. Connect preheater electrical leads and fuel lines.
14. Secure air intake hose to air crossover pipe.
15. Start engine and check for leaks.

V'-350, VT8-430 Engines

1. Remove air pipes from rocker housing cover.
2. Remove vent tubes from crankcase breather.
3. Remove rocker housing covers, and heat shield (if used).
4. Remove spring clip securing spacer halves to rocker shaft, and remove spacer halves.
5. Back off injector adjusting screw and slide injector rocker lever to one side.
6. Remove injector hold-down clamp.
7. Pry injector from cylinder head, being careful not to bruise tip.

Installation

1. Lubricate O-rings with Lubriplate (not lubricating or fuel oil).
2. Start injector into bore, guiding it by hand until injector is aligned in bore and not binding in any manner.
3. Place hammer handle butt on top of injector plunger guide and seat injector by giving a quick hard push on the hammer. A "snap" should be heard and felt as the cup seats in copper sleeve.
4. Install hold-down clamp and torque capscrew to 12/15 ft. lbs.
5. Depress injector plunger with screwdriver by pushing down on plunger top. The injector rocker lever can then be slipped into location. *The plunger link and cup on rocker lever must be engaged, and the rocker lever adjusting screw must seat into push rod socket properly or the injector cannot be adjusted correctly.*
6. Install spacer halves and secure with spring clip.
7. Adjust injectors as outlined in the *Adjustment Section* of this chapter.
8. Position rocker housing covers with new gaskets, and heat shields (if used), and secure with capscrews.
9. Install crankcase breather vent tubes.
10. Install air pipes to rocker covers.

Fig. 4 Oil transfer dowel. C and J Series engines

CYLINDER HEAD

C and J Series Engines

1. Remove rocker lever cover and gasket.
2. Remove intake and exhaust manifolds.
3. If generator is high-mounted, disconnect wiring and remove generator with bracket from cylinder head.
4. Disconnect rubber hose, remove two capscrews, and remove thermostat housing from cylinder head.
5. Remove fuel supply and drain manifolds.
6. Disconnect water tubing from cylinder head.
7. Remove injectors as described above.
8. Loosen all cylinder head capscrews. Remove the seven center (long) capscrews and, temporarily in their place, insert the seven short capscrews. These capscrews will act as a guide in removing rocker lever assembly.
9. Loosen injector plunger adjustment, but let the valve adjustments stand. By not loosening the valve adjustments, it will be easy to turn over the engine when reassembling.
10. Remove four capscrews and three stud nuts holding rocker lever shaft bearings to cylinder head. Using a bar or wooden slat to keep levers in position, lift and remove rocker lever assembly.
11. Remove push tubes from engine.
12. Attach a lifting fixture to cylinder head and to a hoist and remove head from block.
13. Remove head gasket, rubber grommets and brass ferrules and discard them all.

Installation

1. Wipe surface of block with clean, lint-free rag to be sure that no dirt is present.
2. Inspect gasket on both sides to be sure it is clean, and that grommets are not creased. Place gasket on block with "Top" stamp up.
3. Install 24 rubber grommets and the 24 brass ferrules. *The brass ferrules are very thin. Use great care to be sure that only one ferrule is installed over each rubber grommet. If a ferrule is crimped or bent, discard it and install another one.*
4. While head is suspended in air with hoist, and just before lowering it into position, wipe the under-surface with a clean, lint-free rag to be sure that no dirt is present and that excess oil is removed.
5. Lower head into position, guiding it over pilot studs. Lower it slowly so that both ends touch the gasket at the same time and so ferrules and grommets are not disturbed. Remove lifting fixture and hoist.
6. Install push tubes; the largest in diameter is the center or injector push tube.
7. Using a bar or wooden slat to keep the levers in position and the short head capscrews as guides, lower the rocker lever assembly into position. Be sure that the two end studs and the center oil supply dowel are in position on the head, Fig. 4.
8. Remove short head capscrews and install in proper place. Install long capscrews through rocker lever bearings.

NOTE—After the first step in torquing the head, check all rocker levers to be sure that they are free. The end bearings and the center bearing are dowelled into position, but the intermediate bearings are not. These bearings may shift to the extent that the rocker levers will bind on the shaft when the head is tightened. Tighten head as follows:

9. If $\frac{11}{16}$" studs or capscrews, tighten to 280-300 lb. ft. torque. If $\frac{3}{4}$" studs or capscrews, tighten to 380-400 lb. ft. torque. Tighten in rotation shown in Fig. 5. Tighten in rotation the first time around to 25 lb. ft.; second time around to 100 lb. ft.; third time around to the recommended final torque values.
10. Install rocker lever sapscrews and stud nuts and tighten securely.
11. Install injectors.
12. Adjust injector plungers, the valves as described in the *Adjustments Sec-*

Fig. 5 Cylinder head tightening sequence on C and J Series engines (11/16" 280-300 lb. ft.; 3/4" 380-400 lb. ft.)

tion of this chapter.

13. Connect water tubing, fuel supply and drain manifolds, thermostat housing and generator.
14. Install intake and exhaust manifolds. Tighten capscrews and stud nuts beginning at the center and working toward the ends. Tighten exhaust manifold capscrews to 22 lb. ft. in two steps, alternating from top to bottom.
15. Complete the installation by installing rocker lever cover, air piping, electric wiring, water piping and other units removed.

H, NH, NT Engines

1. Remove supercharger outlet connection.
2. Remove fuel connection from intake manifold.
3. Remove intake manifold connection. *Inlet and outlet connections should be kept covered with plates or masking tape to keep out dirt.*
4. Remove intake and exhaust manifolds.
5. Remove water manifold.
6. Remove rocker housing covers.
7. Remove lubricating oil pipe cap and gasket.
8. Remove rocker lever assembly.
9. Remove push rods.
10. Remove fuel lines, fuel inlet and drain connections, and injectors. *Place injectors and inlet connections in proper order on work bench so they will be returned to their original positions.*
11. Remove cylinder heads.

Installation

1. Make sure that cylinder heads on naturally-aspirated engines have the top breather hole open. Supercharged and turbocharged engines must have this breather hole plugged with a 1/8" pipe plug. The breather hole is located at the top of the cylinder head between the center stud holes.
2. Wipe mating surfaces on head and block clean.
3. Install cylinder head gasket with word "Top" to top over studs and oil pipes.
4. Examine oil pipe bore on milled surface of cylinder head for counterbore. If the head is counterbored at this point, install two leather seal washers on each seal oil pipe. If the counterbore occurs at the top surface of the head, install the two leather washers on the oil pipe after the heads have been placed on the block.
5. Oil cylinder head studs and nuts. Tighten each nut slightly in proper sequence as shown in Fig. 6. Continue to tighten in rotation until all nuts have been tightened to 430-450 lb. ft. After engine has been operated approximately 50 hours or 2000 miles, nuts should be retightened.
6. Install injectors and connections.
7. Insert push rods. The injector push rod is the largest and goes in the middle socket. The intake push rods have collars to match with the milled lift of the compression release.
8. On 4-valve engines, assemble crossheads with adjusting screws toward water manifold. Install rocker housing with new gasket.

V6-200, V8-265 Engines

1. Disconnect preheater electrical wires and fuel line from air crossover pipe.
2. Disconnect air compressor suction line from intake air crossover pipe and air inlet hose connections.
3. Drain cooling system.
4. Remove air crossover pipe.
5. Remove valve covers.
6. Loosen locknuts and back off all valve and injector rocker lever adjusting screws.
7. Secure rocker levers together with rubber bands.
8. Unfasten and remove rocker lever assemblies.
9. Remove push rods and crossheads.
10. Remove injectors.
11. Remove air compressor water outlet line.
12. Remove water crossover pipe.
13. Remove thermostat housing from right bank cylinder head.
14. Disconnect fuel supply line from fuel inlet crossover at rear of engine.
15. Disconnect fuel drain line from fuel drain crossover.
16. Remove fuel supply and drain crossovers from cylinder heads.
17. Remove exhaust manifolds.
18. Unfasten and lift off cylinder heads.

Installation

1. Install new head gasket with word "Top" up.
2. Install new O-rings on ring dowels in oil drain drillings. *Do not permit lubricating or fuel oil to come in contact with grommets.*
3. Position head on block over dowels. Lubricate washers and capscrews and secure head to block.
4. Install injectors, push rods, crossheads and rocker levers.
5. Torque head capscrews to 150 ft. lbs. in 50 foot-pound increments in the sequence shown in Figs. 7 and 8. Final tightening should be 155-160 ft. lbs.
6. Install exhaust manifolds.
7. Connect fuel supply and drain crossovers to cylinder heads.
8. Connect fuel drain line to fuel drain crossover.
9. Connect fuel supply line to fuel supply crossover.
10. Adjust injectors, crossheads and valves as outlined in the *Adjustment Section* of this chapter.
11. Install thermostat housing, water crossover pipe, valve covers, air intake crossover pipe, and connect air compressor air and water inlet lines.
12. Connect air inlet hose connections to air crossover pipe.
13. Connect preheater electrical wires and fuel lines to intake air crossover pipe.
14. Fill cooling system, start engine and check for leaks.

Fig. 6 Cylinder head tightening sequence on H and NH engines (430-450 lb. ft.)

Fig. 7 Cylinder head tightening sequence. V6-200 engine

Fig. 8 Cylinder head tightening sequence. V8-265 engine

V8-350, VT8-430 Engines

1. Drain cooling system.
2. Remove intake manifolds, exhaust manifolds and rocker covers.
3. Loosen all injector and valve adjusting screws. Tie all levers together or secure with rubber bands to prevent separation.
4. Remove rocker lever assemblies.
5. Remove injectors.
6. Lift push rods from tappets.
7. Unfasten and lift off cylinder head, using a suitable hoist.

Installation

1. Four breather holes are drilled in the top of each cylinder head. On the right bank side two holes are located above No. 1 cylinder and two above No. 4 cylinder. On the left bank side two holes are located above No. 5 cylinder and two above No. 8 cylinder.
2. On naturally-aspirated engines the breather holes in line with the intake manifold ports *must* have ventilator

plug installed. The hole in line with the exhaust manifold port *must be plugged* with a 1/8" pipe plug.

3. On turbocharged engines all breather holes *must be plugged* with 1/8" pipe plug.
4. Place grommet retainers in water passages in block, *small end up.*
5. Lay gasket on flat surface and press grommets into place by hand. *Avoid all contact between grommets and fuel or lubricating oil to prevent damage.*
6. Install head gasket with word stamped 'Top" up. Be careful not to dislodge grommets as gasket is lowered over grommet retainers.

Fig. 9 Cylinder head tightening sequence. V8-350 and VT8-430 engines

7. Lower head into position.
8. Oil cylinder head capscrews and tighten each slightly in the correct sequence shown in Fig. 9.
9. Insert push rods in tappets.
10. Install injectors in cylinder head and torque capscrews to 12/15 ft. lbs.
11. Position rocker levers on cylinder head. Align all push rods to rocker lever adjusting screws. Secure with capscrews by tightening slightly.
12. Continue tightening in proper sequence and in 30 foot-pound steps until all capscrews have been tightened to 170/180 ft. lbs.
13. Adjust valves and injectors as outlined in the *Adjustment Section* of this chapter.
14. Install intake and exhaust manifolds and rocker covers.
15. Fill cooling system and check for leaks.

Unit Repair Section

ROCKER LEVERS

All Engines—If rocker lever bushings are worn larger than 1.1265", new bushings should be installed and bored to 1.1245-1.1255". The ball end of rocker lever adjusting screws must be true spheres. Test them with a 1/4" radius gauge. If worn flat they must be replaced.

The injector rocker lever sockets must be replaced if excessively worn. Wear is easily detected with a radius gauge or by a small protrusion at the bottom of the socket. These sockets must seal with injector links in the assembled engine to prevent loss of lubricating oil to the fuel oil drain.

C and J Series Engines

To disassemble, place the rocker lever assembly on the work bench and remove the dowel pins from each end bearing of the shaft. Remove all bearings and rocker levers from the shaft. Remove the socket end plugs from each end of the shaft.

When assembled, be sure all lubricating passages in rocker levers, rocker lever sockets, oil line dowel pin (center bearing) and rocker lever shaft are clean and unobstructed.

Fig. 1 Removing or installing tappet guides. C and J Series

H and NH Engines

To disassemble, remove the set screw that holds the rocker arm shaft to the housing. Remove the expansion plug at each end of the housing. Use a sharp pointed punch to drive through the plug on one end and drive the shaft through to force the second expansion plug out of the housing.

When an old style smooth shaft is replaced with new style grooved shaft, the position of the lock screw must be changed to the underside of the housing.

Any play of rocker lever rollers on pins is cause for replacement of pins. Rollers must be replaced if worn flat at any point or if the pin hole is worn beyond .346". Pins and rollers can be removed by grinding the peened end of the rivet and pressing out the rivet and pins with punches. Rocker levers must not be used if bored holes for rollers pins are distorted enough to throw the roller out of alignment with the shaft bushing.

PUSH RODS

C and J Series Engines

Each cylinder has three push rods, exhaust, fuel and intake. The intake push rods have a lift which coincides with the milled recesses in the compression release shaft. When the compression release lever is pulled upward, the intake valve is held open, permitting the engine to be cranked easily.

Check both ends of all push rods. The upper ball seat and the lower ball end must be true polished spherical contours. The upper end has a spherical inside diameter of .4995-.5005". The lower ball diameter is .685-.687" with a 1/8" diameter flat at the bottom. Replace rod if either end is worn or shows signs of scratching or galling.

H and NH Engines

Like the J engine, each cylinder has three push rods, exhaust, intake and fuel. The ball of a new fuel push rod is .748-.749" diameter and is ground to true spherical contour. If the end of the ball is worn flatter than .500" radius, it should not be used.

The lift or collar of intake push rods must not be so badly worn that there is danger of its not functioning with the compression release lever.

Test the sockets of push rods with the ball end of a new rocker lever adjusting screw or with a 1/4" radius gauge.

Extreme wear on either end of the push rod will result in loss of lubricating oil pressure and may interfere with proper valve and injector adjustment.

INJECTOR SLEEVES

All Engines—Injector sleeves must seal in the cylinder head to prevent water leaks. The injector seal must seal with the injector cup to prevent compression leaks. Special equipment, available through Cummins Dealers, is necessary for injector sleeve replacement.

VALVE SEAT INSERTS

All Engines—If inspection shows that valve seat inserts are loose, or if valve seats are wider than .125" and cannot be narrowed sufficiently, new inserts should be installed.

Remove old inserts with a valve seat puller or with a punch through the ports. Cummins service tools are available for

Fig. 2 installing cam rocker lever assembly. H and NH engines

Fig. 3 Valve timing marks. C and J Series Engines

installation of new inserts. The counterbore must be enlarged for the next oversize. Cutters are available in sets for each engine.

Counterbores for valve seat inserts should be machined .006-.010" deeper than the insert height to permit peening of head to hold insert. A ¼" diameter roundend punch can be used to peen inserts. Avoid over-swaging around the inserts as this may cause a cast iron ring to be broken from the cylinder head.

Valve seats in standard and .005, .020, .030 and .040" oversizes are available.

VALVE GUIDES

All Engines—If valve guides need replacing they can be driven out from the underside of the head. New valve guides can be installed by pressing them in from above. Use a hardwood block or proper size mandrel to prevent distortion.

VALVE CROSSHEAD GUIDES

Four-Valve Engines

New crosshead guides are made to size and it is not necessary to remove any material. Check size with a new crosshead stem and if there is any binding, ream the guides to .3755-.376".

VALVE & INJECTOR TAPPETS

C and J Series Engines

The valve and injector tappets ride directly on the cam to operate valves and injectors. The tappets are guided through machined bores in the block. New valve tappet-to-bore clearance is .002". Injector tappet-to-bore clearance is .003".

The tappet bores are accessible through the push rod opening in the block.

The injector tappet guides, located in the side of the block and held in place by snap rings, are removed and installed by inserting a $\frac{5}{16}$"-18 capscrew as a means of removing and installing the guide, Fig. 1. The injector tappet is kept from turning by the guide which fits into the slot of the injector tappet. When installing injector tappet guides, place the rubber "O" ring in the groove of the guide and insert in the block. Lock the guide in place with a snap ring.

CAM FOLLOWERS

H and NH Engines

To disassemble the cam follower housing and levers, remove the set screws that hold the shafts in the housing. Drive out the expansion plugs, using a punch to drive through one plug and then drive the shaft through the housing to remove the other expansion plug.

If the shafts are worn smaller than .748", replace with new style ungrooved shafts. Gauge cam follower lever bushings. New or newly replaced and bored bushings must gauge .7495-.7505". If old bushings are worn larger than .7515", the levers must be rebushed with new style two-piece bushings. The two-piece bushings must always be used in combination with new style ungrooved shafts.

Since rollers of cam follower levers act directly on the camshaft lobes, it is extremely important that proper alignment of lever shafts, rollers and camshaft lobes be maintained. A small amount of misalignment will cause uneven and excessive wear on camshaft lobes, particularly of the injector cam lobe. If proper lever length is not maintained or restored in rebushing the levers, it will be impossible to time the engine properly.

Use a new gasket and assemble the lever and housing assemblies to the cylinder block. Secure with lockwashers and capscrews. A flat head screw and star lock washer must be used in the top middle hole of No. 1 housing to provide clearance for the compressor drive belt on NH Series engines.

When pressure is applied on cam follower levers, the lever rollers must bear evenly on the camshaft lobes. This alignment can easily be checked with Prussian Blue.

INJECTOR TIMING

H and NH Engines

The gasket thickness between the cam follower lever housing and the cylinder block regulates injection timing, Fig. 2. The reason is that the cam follower rollers do not ride directly over the top of the cam lobes. Pulling the levers away from the block (adding gasket) advances timing on right-hand engines, and vice versa. Use gaskets as needed to get the correct timing.

All H and NH engines should be timed with Cummins fixtures ST-300 which, among other components, includes two special dial indicators. Cummins Dealers have this fixture available for use along with complete procedure on how to use it to time the engine.

TIMING GEARS

C and J Series Engines

For correct valve timing, install the camshaft gear so the "O" mark on the cam gear indexes with the "O" mark on the crankshaft gear, Fig. 3.

The fuel pump is driven through the air compressor by the accessory drive gear. For this reason the accessory drive gear must be timed with the cam gear as follows, Fig. 4.

Remove the plug from the timing view hole in the gear case cover and, with the aid of a pencil light, assemble the accessory drive in place with the "O" mark on the gear matched with the center punch mark on the camshaft gear.

Fig. 4 Timing accessory drive gear to camshaft gear. C and J Series engines

H and NH Engines

All camshaft gears are marked with an "O" which indexes with the "O" on the crankshaft gear for correct valve timing. The camshaft gear also has a center punch, or dash marks, which index with the punch-marked tooth of the fuel pump or fuel pump drive gear.

Formerly the punch marks were 35 to 37 teeth from the "O" mark and all fuel pumps were installed at the No. 1-6 Top Center position.

Beginning with Engine Serial No. 72125, the punch marks were changed to dash marks and retarded 9 teeth. The dash marks are now located 26 teeth for right-hand engines or 28 teeth for left-hand engines from the "O" mark and in gear rotation direction. Check cam gear markings and, if the gear has the obsolete marking, remove the old center punch marks and make new dash marks 9 teeth back of the marks removed to agree with current gear marks.

SUPERCHARGER IDLER GEARS

J Series Engines

It should not be necessary to rebuild the supercharger idler gear assembly unless it has become noisy or loose, indicating broken leaf springs inside the assembly or worn bushings.

If necessary to disassemble, remove the six capscrews and the idler drive hub, blower gear, thrust washer and the spring retainer cover. Carefully pry and remove the 10 idler leaf springs, four spring retaining pins, and separate the idler driven gear from the spring retainer.

To repair the unit, replace all damaged leaf springs. Check the idler gear bushings and the three idler hub bushings. New idler gear bushings are 2.126-2.125" inside diameter with bushings pressed in place. New idler hub bushings are 1.501-1.500" inside diameter with bushings pressed in place. The idler gear shaft is 1.4985-1.4975" outside diameter. Check thrust washer for wear or galling.

Assemble in the reverse order of disassembly, using extreme care when installing the idler leaf springs as they could easily cause a serious injury if they are allowed to fly loose as they are forced between the gear cam and spring retainer, Fig. 5.

To install the assembly, place idler driven gear with its idler drive gear over the idler gear pin. Be sure the inner thrust washer is properly indexed to the three head bolts before assembling the gear on the journal. Fit the outer thrust washer to the gear hub and bring the cover washer in place by tightening the capscrew over the washer. The clearance between the thrust washer and gear should be .007-.019".

PISTONS

All Engines—Worn pistons should not be reused if the ring-to-groove side clearance with new rings is in excess of .006" when the outside surface of the new ring is flush with the adjacent ring land surface.

Fig. 5 Installing idler leaf springs in supercharger gear. J Series engines

Maximum piston diameter is measured at the piston skirt and at right angle to the piston pin. This dimension subtracted from the cylinder liner inside diameter gives piston-to-liner clearance.

Pistons are available in standard and .020, .030 and .040" oversizes.

Reboring of piston pin holes and use of oversize pins is not practical because the misalignment that results from such practice will cause seizure of piston or failure of connecting rod bearings.

Cummins pistons prior to Serial No. 88098 were equipped with injector cup wipers, or sneezers. The purpose of the sneezer is to provide better combustion and to prevent carbon from forming on the injector cup spray tip. The sneezer is screwed into the head of the piston. After Serial 88098 new aluminum pistons do not have the sneezer. Pistons with and without sneezers must not be mixed in any engine. The sneezer, if used, must be installed and locked with lock plate No. 60026. If the sneezer comes loose during engine operation, it will cause extensive damage.

CYLINDER LINERS

All Engines—Several types of failures can result when liners have been improperly installed, most serious of which would be scored liners and seized pistons. The following instructions should be carefully followed:

1. Make sure that all mating surfaces of liner and block have been thoroughly cleaned.
2. Place the liner, without packing rings, into the block. It should drop into position of its own weight. The liner must always seat freely in the block. Test liner-to-block clearance by shaking. If there is no detectable clearance, remove the liner and make sure both liner and block bore are perfectly clean. If necessary, scrape the block bores and counterbores until the liner does seat freely.
3. Check the clearance around the entire circumference of the block counterbore and the top liner flange with a .002" feeler gauge.
4. Check liner flange and counterbore depth in the block. Flange must be .004 to .006" above surface of block when assembled. Steel shims are available to obtain this protrusion. The shims are .002", .007", .008" and .009" respectively.
5. If the liner flange counterbore is not smooth or straight, the cylinder block should be sent to a Cummins Dealer Shop where a special counterbore tool can be used to straighten the bore before the shims are installed.
6. To install the liner, put on the rubber packing rings, being careful not to stretch them.
7. Lubricate the packing rings and the machined portions of the block on which the rings seat with clean lubricating oil or ball bearing grease.
8. Assemble the liner in the block and push it into place with hand pressure only. Check the liner at several points down the length of its bore with a dial bore gauge or inside micrometers to see that it has not collapsed due to being tightly fitted. New liners must not be out-of-round more than .001" when installed.

PISTON RINGS

All Engines—Each piston carries three compression and one oil ring. Be sure to use the type ring specified for the piston.

Piston ring gap is checked with the piston ring in its mating cylinder liner. It may be necessary to file the ends of the rings to obtain the minimum ring gap clearance during assembly.

Rings are available in standard and .020, .030 and .040" oversizes.

PISTON PINS

All Engines—Clearance of piston pins in new cast-iron pistons is a thumb push fit with parts at room temperature (70°). Aluminum pistons should be heated in boiling water before installing the pins.

ROD BEARINGS

Rod bearings are the precision shell type which must never be scraped or reamed. Undersize shells are available in .005 (JS), .010, .020, .030 and .040". Shells should not be reused if worn thinner than .071" on J engines or .070" on H and NH engines.

Cummins recommends tightening rod

Fig. 6 Assembling spindle to oil pump idler gear. C and J Series engines

bearing cap nuts by the template method as follows:

C and J Series Engines

1. Oil threads and lock plates.
2. Tighten nuts on each side of both U-bolts alternately and in 5 lb. ft. increments to 25-30 lbs. ft. This torque is used to avoid permanent stretching of the bolts during the initial tightening.
3. Loosen nuts completely.
4. Retighten nuts alternately in steps of 5 lbs. ft. to 25-30 lbs. ft.
5. Draw a thin pencil line on each nut to coincide with the permanent marks on the cap. If caps are not marked, extend a line from one hex of each nut to the cap.
6. Advance each nut one hex or 60°. In order to prevent U-bolts from becoming misaligned, advance alternately in steps of 30° until 60° is reached.
7. Lock nuts in place.

H and NH Engines

1. Use new lock plates and oil the lock plates and threads.
2. Tighten nuts to 140 lbs. ft. This is not operating tension.
3. Back off nuts at least one full turn to release all tension.
4. Retighten the nuts to 50-55 lbs. ft. This should be done in two steps to insure even tightening.
5. Tighten each nut an additional 60°. This is equivalent to advancing the nut one hex face beyond the position obtained in Step 4.

MAIN BEARINGS

All Engines—New standard main bearing shells are .123-.12375″. Shells should not be reused if worn thinner than .1215″ or .002″. Undersize bearings are available in .010, .020, .030 and .040″.

Main bearings may be replaced in the conventional manner without removing the crankshaft. Cummins recommends tightening main bearing cap nuts by the template method as follows:

1. After shells and caps are properly placed, oil the stud and nut threads.
2. Install new lock plates.
3. Tighten nuts to 160 lbs. ft. on J engines or 320 lbs. ft. on H and NH engines. This step is only used to settle the shells, caps and lock plates.
4. Loosen nuts completely.
5. Retighten nuts to 30-35 lbs. ft. on J engines or to 140 lbs. ft. on H and NH engines.
6. Advance the nut 60° or one hex face from the snug position on J engines, or 30° or ½ hex face on H and NH engines. Tighten each side of the bearing a little at a time, bringing both sides up as evenly as possible. This is the operating tension.

CRANKSHAFT END PLAY

C and J Series Engines

The rear main bearing consists of two shells and four thrust half-rings. The thrust half-rings, like the shells, are interchangeable.

The thrust half-rings are held in place by dowels in the cap—two for each half-ring—and by counterbored recesses in the block and cap. The grooved babbitt faces fit next to the crankshaft flanges.

Crankshaft end clearances for new bearings and a new shaft will be .004-.009″. Worn shafts and thrust rings should not be reused if end clearance is in excess of .022″. Check end clearance as follows:

1. Attach a dial indicator securely to the cylinder block with the contact point of the gauge resting on the crankshaft flange end face.
2. With a small bar, pry the crankshaft toward the front of the engine and set the gauge at zero. Then pry the crankshaft toward the rear of the engine.
3. If the clearance is less than .004″, loosen the nuts slightly and shift the crankshaft first toward the front end of the engine and then toward the rear.
4. Retighten the nuts by the template method outlined previously and recheck the end clearance.

H and NH Engines

Procedure for checking crankshaft end play is similar to that outlined above except that the limits are .007″ to .013″.

CRANKSHAFT REAR OIL SEAL

All Engines—The rear cover has a braided asbestos seal around the crankshaft. When the rear cover is assembled to the cylinder block, its bore must be in line with the main bearing bore.

Cement a new gasket over the dowel pins on the rear of the cylinder block. Assemble the upper cover plate over the dowel pins and tighten the four capscrews. With the crankshaft pried toward the cover plate, check the clearance between the crankshaft flange and the opposing face of the cover plate. Clearance should be a minimum of .004″.

The .004 to .008″ (.004-.006″ on J) clearance can be obtained by the use of .005″ and .010″ gaskets to move the cover plates to or from the cylinder block.

The clearance between the crankshaft and bore of the cover plate should be .009 to .011″ (.006″ on H and NH) around the entire circumference. This clearance is provided when the original rear cover is installed at the factory and maintained by locating dowels. This can be checked after the old asbestos seal has been removed by using a .009″ feeler gauge between the shaft and upper cover.

Remove the cover plate and install new asbestos seals into the recess of both upper and lower cover plates. New seals must be beveled on three sides of each end, $\frac{1}{32}$″ by 45°, leaving the inside edge square. The ends of the seals should extend $\frac{1}{32}$″ above the joining surfaces of the cover plates. Seals should be soaked in lubricating oil an hour or more before installing. Make sure they are well seated in their grooves.

Cement new connecting gaskets to the lower cover plate. Assemble the lower plate to the upper plate and bolt together tightly. Install capscrews to cover plates and pull up evenly to the cylinder block over the dowel pins.

LUBRICATING OIL PUMP

C and J Series Engines

The lubricating oil pump is the gear type located in the crankcase below the crankshaft. It is driven by an idler gear off the pinion gear.

Excessively worn parts or assemblies must be replaced. Bushings and bodies should be replaced as assemblies because bushings must be properly located and line-bored.

When new, the pump parts have the following dimensions: Idler and driver shaft bushings .6165-.6175″. Idler and

driver shaft outside diameter .6150-.6155". Idler gear bushing .9925-.9935". Idler gear spindle .990-.991".

1. To assemble the pump, place the driver gear over the shaft with the marked end to the oil inlet side of the body.
2. Assemble the driver gear and shaft to the cover. Then press the drive gear to the shaft, leaving .002" clearance between gear and cover.
3. Assemble gasket and cover to pump.
4. Assemble spindle to idler gear, Fig. 6.
5. Assemble thrust washer with its locking lip matching the milled recess in the pump cover.
6. Assemble the idler gear and spindle to the cover. The spindle is dowelled to the cover with two dowels. These dowels are a press fit in the cover and should protrude approximately $\frac{5}{16}$" into the spindle.
7. Assemble the by-pass valve plunger, spring, spring retainer to the body with the clamp provided.

H and NH Engines

The standard oil pump in these engines is of the two-gear type. In servicing these pumps, note the following:

1. The ball bearing outer race must not turn in the ball bearing cage.
2. The gears must show no excessive wear, or be scored or otherwise damaged.
3. The drive shaft must be replaced if it has been turning in the inner race of the ball bearing; if it is worn smaller than .8735" where it bears against the bracket bushing, or if it is worn smaller than .8705" on the body end.
4. The bracket bushing should not be used if its inside diameter is worn larger than .887".
5. Idler pins should be replaced if worn smaller than .873".
6. Replace bracket or cover if finished surfaces are scored or visibly worn larger than 2.301" inside diameter. Maximum gear to pocket clearance should never exceed .008" or .004" on a side.
7. The by-pass valve in the body should not open below 75 lbs.
8. When assembling the pump, the pump gear should be pressed on the shaft so there is a clearance of .0015" between the gear and bracket.

Fig. 9 Water pump. H and NH engines

Fig. 7 Lubricating oil strainer head and pressure regulator. C and J Series Engines

LUBRICATING OIL PRESSURE REGULATOR

C and J Series Engines

The lubricating oil strainer head contains the lubricating oil pressure regulator, Fig. 7, and the strainer by-pass valve.

1. To disassemble, remove the large retaining nuts from each side of the strainer head, then remove the spring and plunger.
2. The pressure regulator maintains a constant lubricating oil pressure of 30-50 lbs. at governed speed.
3. Mark the plunger, plunger spring and retaining nuts to assure reassembly in the same order as removed. If the plunger is assembled backwards, oil pressure will build up to 125 lbs.
4. Check the regulating plunger for free action and for wear. The diameter of the plunger should be .740-.741". If worn smaller than .738", install a new plunger.
5. The regulating spring should compress to 1.620" at 13-lb. load.
6. The strainer by-pass valve opens when the strainer becomes dirty and clogged and allows unfiltered oil to pass through the system. The by-pass valve opens at 15 lbs. differential pressure. Check the by-pass valve spring, ball and ball seat to see that they are functioning properly.
7. The restrictor plug opens to the oil header and determines the position of the pressure regulator. Be sure the $\frac{1}{16}$" hole in this plug is clean and unobstructed.

Fig. 8 Water pump. C and J Series Engines

LUBRICATING OIL COOLER

All Engines—To prevent hardening and drying of accumulated foreign substance, the core of the oil cooler should be cleaned as soon as possible after removing from service.

On tubular-type coolers, remove the oil by-pass valve and body from side of cooler. Then take off the front and rear cooler heads and gaskets.

If a plate-type cooler is used, remove the oil cooler cover and take out the core. Loosen the large hex nut from the cover and pull out the spring and plunger of the by-pass valve.

On the oil side of either type cooler, immerse the core in a container of carbon "tet" or some other suitable solvent. After the core has been allowed to stand in solvent for several minutes, force the cleaner through the tubes with an ordi-

nary hand rubber suction cup or with a hand or motor driven pump in the reverse direction from the operating flow. Continue the action until the unit is clean. The oil side of the cooler should always be cleaned before the water side. This operation should be done in the open air or in a well ventilated room to avoid toxic effect of the chemicals being used. An oakite or alkaline solution is recommended, particularly where the oil passages are badly clogged. This should be circulated through the tubes. After cleaning, flush thoroughly with hot water. Flush the inside of the oil tubes with clean, light oil after the oil and water sides of the cooler have been cleaned.

WATER PUMP

C and J Series Engines

The water pump, Fig. 8, is the sealed type, mounted to the rear of and driven by the supercharger. The pump is serviced in the conventional manner. However, when pressing the impeller on the shaft, its face should be .870-.880″ below the cover mounting face of the pump body. If the impeller is pressed on too far, it will lock.

When filling the housing with grease be sure to remove both plugs to prevent building up pressure inside the housing and damaging oil seals.

H and NH Engines

Fig. 9 shows the construction of a typical water pump used on these engines. It is serviced in the conventional manner. When the impeller is pressed on the shaft there should be a distance of 2.000″ from the inside surface of the pump body mounting flange to the outer face of the impeller as shown. Assemble seal and related parts in the order shown in Fig. 10.

INJECTORS

Fig. 11 illustrates a fuel flow diagram for the PT Fuel System, while Fig. 12 is a view of an injector. The injector is a simple mechanical unit which receives fuel from the fuel pump and injects it through the fine spray holes of the cup into the combustion chamber.

Fig. 10 Installing seal and related parts. H and NH water pump

Fig. 11 PT Fuel System fuel flow diagram

While servicing injectors, never clamp the body in a vise as this practice usually causes distortion of the body and ultimately a sticking plunger. Use a holding fixture similar to that shown in Fig. 13.

Disassemble

Place injector in holding fixture, Fig. 13. Remove injector plunger retainer bail or screw. Remove injector cup.

Cleaning

In the PT system fuel metering is a dual function of the pump which regulates fuel pressure and the injectors which permit the metering orifice to be uncovered for an accurately controlled period of time. Any change in the *pressure, orifice or time,* will affect the amount of fuel delivered to the combustion chamber.

There are two things which will interfere with the normal functions of injector orifices: (1) dirt or carbon accumulation in the orifices or passages to and from orifices; (2) changing size or shape of orifices, particularly by wrong cleaning methods.

Always soak dirty injectors in a good carbon solvent such as Bendix Metal Clean to remove carbon. After soaking, dip in a neutral rinse such as mineral spirits and blow clean with compressed air. *Never use cleaning wires in orifices.* In a few cases engines have lost as much as 40% of their rated horsepower because of dirty or carboned orifices, and the lost horsepower was regained after proper cleaning. *Practically all cases of carboned orifices are due to incorrect injector adjustment.* For adjustment, see *Adjustments Section* of this chapter.

A strong magnifying glass can be used to check for burrs and distorted radii in orifices. When injector orifices are damaged by wrong cleaning methods, the injector cannot be made to function properly.

Fig. 12 Injector used with PT fuel system

Fig. 13 Injector holding fixture

Fig. 14 Checking injector for leakage at plunger, using Cummins ST-272 injector test stand

Checking Injector For Wear

Worn injectors may cause dilution from excessive body-to-plunger clearance. It may occur as a result of a cracked injector body or cup, or from damaged "O" rings. A special injector test stand was developed by Cummins for testing injectors. In using the test stand, the procedure is as follows:

1. Assemble injector.
2. Plug off inlet and drain connection holes.
3. Mount injector in test stand, Fig. 14, with cup in bronze seat and with plunger lifted .045" off its seat.
4. Test at maximum of 1000 psi with fuel flowing upward through the cup spray holes.
5. If counterbore at top of injector body fills with fuel in less than 10 seconds, the plunger clearance is excessive and might cause dilution in the engine.
6. During this check inspect injector for leaks around the cup, body and plugs.
7. If injectors do not pass the test, correction must be made by installing new parts, checking assembly, or return of injector to the factory for refitting of plungers.
8. Worn plunger links can be removed by breaking the ears off the retaining ring. Then install new parts.
9. At any time an injector plunger is removed, lubricate it with a thin coat of Molycote Type M-55 (ready mixed) or a mixture of lubricating oil and Molycote Type Z.

Relieving Cup and End

If the cup end of J, H, NH and NVH series injectors are not relieved as shown in Fig. 15, the relief should be added. Addition of the relief will improve cup gasket-to-body contact and give an improved seal. Special Cummins cutters are available for performing this operation. The center of the cutter acts as a stop to prevent cutting too deep. The relief should be .005" to .010" deep.

When injector cups are installed on J, H, NH and NVH series injectors with the relief, tighten cups to 60 lb. ft. with a torque wrench.

Replacing Injector "O" Ring

The injector cup "O" ring should be replaced with a new one each time the cup is removed. Install an "O" ring assembly sleeve, Fig. 16, over the threaded end of the injector body. Dip the "O" ring in lubricating oil and slide it over the sleeve into the groove on the injector body.

Installing Injector Cups

Overtightening injector cups will distort the cup and prevent injector plunger from seating properly. Undertightening may cause engine to misfire.

Tighten cups on bodies with a torque wrench. An adpater wrench is available for use with a socket and torque wrench. Tightening values are as follows:

Wrench Adapter	Injector Cup	Tighten To
ST-500	L and LR	300 lb. ft.
*ST-499	J, JS, JT	60 lb. ft.
*ST-498	All Others	60 lb. ft.

*Injectors with relief, Fig. 15.

If the injector plunger does not seat properly in the cup, change the cup rather than try to lap the plunger and cup together. Lapping will change the relationship between plunger groove and metering orifice, and disturb fuel metering.

Always use a new injector cup gasket when cup is assembled to body to avoid distortion of cup. When the cup is tightened to the body the gasket compresses everywhere except under the milled slots on the end of the body. Then, if reused, the uncompressed areas may cause the cup to cock and prevent the plunger from seating properly.

Tighten plunger retaining screw to a torque of 40 inch lbs.

PT FUEL PUMP

When fuel pumps are repaired or rebuilt the work must be done by specially trained mechanics in a properly equipped shop. Cummins Dealer's facilities are available or he will provide the necessary tools, equipment and necessary information required to do the work in your own shop. For general field service, however, the following operations can be performed.

Fig. 15 Relief on injector body

Fig. 16 Installing "O" ring on injector

Fuel Pump Screen

The fine mesh fuel filter screen in the pump, Figs. 17 and 18, should be removed and cleaned each 1000 gallons fuel consumed to prevent unnecessary wear and loss of power. A clogged filter screen will cut down fuel delivery to the engine. It is good practice to clean this filter after 5 to 6 hours operation when the fuel pump is first put into service. This is to remove particles of gasket cement which may have been used in connections between the pump and engine fuel filter.

The filter screen is located under the large cap on top of the fuel pump. It can be removed by loosening the cap and lifting out the spring and screen assembly. The screen can be separated from one of the screen retainers for easy cleaning; the other retainer is soldered to the screen. Replace the screen and retainer, with the retainer with the hole facing down. The spring is assembled on the screen, the cone end of the spring may be assembled either up or down. The cap must be tightened to 20-25 lb. ft.

Priming the Pump

No priming is required under normal

Fig. 17 Exterior view of PT fuel pump (automotive type)

conditions. However, the first time a "dry" pump is hooked up a few squirts of clean lubricating oil in the gear pump will aid in quicker pick up of fuel.

Fuel Filter

The majority of low power complaints are caused by dirty fuel filter elements. A dirty element restricts fuel flow in varying degrees and may stop flow entirely.

The element must be changed as often as necessary to maintain a full fuel flow. The change periods will vary according to the fuel used but the average is once every 400 to 500 hours of operation.

1. Loosen capscrew at top of fuel filter and lower filter case from top cover.
2. Take out dirty element, clean filter case, and install a new element.
3. Install a new filter cover gasket, dip gasket in fuel oil before installing so cover will seat smoothly.
4. Fill filter case with clean fuel for faster pump pick-up and tighten cover capscrew securely to prevent air leaks.

Fig. 18 Sectional view of PT fuel pump (automotive type)

SUPERCHARGER, J ENGINES

Fig. 19 illustrates the construction of the supercharger. Check the condition of the air outlet port. An excessive amount of oil in this port indicates that the piston ring oil seals on the rotor shaft may be worn or broken or oil may be coming over to the supercharger inlet through the breather line from the engine valve cover. If an inspection of the breather line does not show evidence of oil, then the supercharger should be completely disassembled for a closer inspection of the piston ring oil seals.

Check the radial clearance in the bearings by mounting a dial indicator as shown in Fig. 20. Clearance should not exceed .003". To make this check, it is necessary to flush the oil out of the bearings so that a reasonably accurate measurement of the bearings can be obtained. First remove the pump-end cover and force diesel fuel under pressure through the supercharger oil inlet until the bearings are flushed free of lubricating oil. Then, if radial movement exceeds .003", the supercharger must be disassembled.

Check end play of the rotor shaft by mounting the dial indicator as shown in Fig. 21. If total end play of either rotor shaft exceeds .005", the supercharger must be disassembled.

Check timing gear backlash with dial indicator mounted as shown in Fig. 22. If backlash between gears exceeds .004", install a new set of gears.

Fig. 19 Cutaway view of Supercharger on J Series engines

Fig. 25 Checking width of bearing cage. J Series supercharger

Fig. 26 Checking hub length for end play. J Series supercharger

Fig. 27 Checking rotor end clearance J Series supercharger

Disassembly

1. With special lock nut wrench, Fig. 23, remove rotor shaft lock nuts. Use a piece of brass or copper rod wedged between the timing gear teeth to lock the gears while loosening the lock nuts.
2. Remove pump end plate.
3. Remove housing from gear end plate.
4. Press off gears, Fig. 24.

Rebuilding

1. Piston ring seals on rotor shafts, if broken, should be replaced. Clean out ring grooves and check for excessive or visible groove wear. Insert new rings with a piston ring expander.
2. Excessive wear or roughness in piston ring bores in end plates will not allow piston rings to seal properly in which case the end plates should be replaced.
3. If the bearing bores in each bearing cage exceeds 1.3765″ diameter the bearing cage should be replaced. Note that shims are used on the gear end bearing cages under the mounting flange. These shims control the end clearance of the rotors in the housing. Mark each cage so that it can be replaced in the same pocket from which it was removed and tie each set of shims with its respective cage. If new bearing cages are to be installed, this precaution is not necessary.
4. The end thrust can be checked by measuring the bearing cage width and the distance from the thrust face of the gear to the end of the gear hub. The bearing cage width must be .001″ to .005″ less than the gear hub, Figs. 25 and 26. If the difference between these two dimensions is greater than .005″, the end thrust is too great. New gears, thrust washers and bearing cages should be used.
5. If the water pump drive coupling on

Fig. 28 Oil seal rings (on each end of housing). J Series supercharger

the rotor shaft shows excessive wear, it should be replaced.

6. For other repairs, such as broken or cracked rotors, shafts or housing, the supercharger should be returned to the factory for rebuilding.

Assembly

1. Install piston ring oil seals in grooves on rotor shaft, using a ring expander. Ring gaps should be held to .001 to .002".
2. Press water pump drive coupling on rotor shaft extension up tight against the shoulder on the bearing journal.
3. Install thrust washers in gear end plate and replace bearing cages. If new bearing cages are to be installed, use .005" total shim thickness under each bearing cage. This amount may have to be adjusted later when the rotor end clearance is checked.
4. Use new rubber seal rings on each bearing cage. Leaving these rubber rings out will cause loss of oil pressure and result in burned out supercharger bearings.
5. Insert splined shaft of driving rotor through bottom hole in gear end plate, using care not to damage piston ring seals.
6. Press on timing gear.
7. Insert idler rotor through second hole in gear end plate and press on other timing gear. Make certain that the rotors are positioned 90° apart as the gears come into mesh.
8. Press drive gear on shaft up tight against timing gear.
9. Slip outboard bearing on shaft.
10. Tighten lock nut and washer on each rotor shaft.
11. Check clearance between rotors and end plate, Fig. 27, which should be .003" with no end play. If more than .003", shims will have to be added under the bearing cage mounting flange. If less than .003", shims should be removed until proper clearance is obtained.
12. After proper end clearance is obtained, install housing to end plate. Use new rubber seal rings on the oil pressure and drain line ferrules, Fig. 28.
13. Replace pump end plate to housing, using new rubber seal rings on oil pressure and drain line fittings.
14. After installing cover to end plate, turn rotor shaft by hand to see that it rotates freely.

Fig. 29 Supercharger. H and NH engines

SUPERCHARGER, H & NH ENGINES

Fig. 29 shows the construction of the supercharger used on these engines. If the supercharger rotors or case are scored or broken, it is best to get a factory rebuilt unit. This inspection can be made through the inlet and outlet ports, thus eliminating useless disassembly.

In addition to the hand tools that are available to the average mechanic, certain special tools must be used in replacing bearings and oil seals. To overhaul the supercharger completely, Service Tool Kit No. ST-107 is available through your Cummins Dealer.

After the supercharger is disassembled, clean and inspect all parts. Any broken or excessively worn parts must be replaced with new ones. The following parts should always be replaced with new ones whenever the unit is disassembled: all bearings, oil seals, bearing cover gasket, gear cover gasket and four rotor shaft lockwashers.

Inspect the rotors, housing and end plates for cracks, abrasions, wear spots and build-ups of foreign material. Cracked castings should be replaced with new ones. Rough or worn spots should be smoothed out with fine emery cloth and all deposits of gum, carbon, etc., should be removed. The parts should then be washed clean and dried. Rotors and shafts are not separable and must be replaced as a unit. Check the following parts for excessive wear:

1. Generator flange should be replaced if the hub diameter is visibly worn or grooved under the oil seal, or if the sprocket teeth are worn or broken.
2. Drive coupling should be replaced if the hub diameter is visibly worn or grooved under the oil seal.
3. The rotor timing gears should be checked for backlash with gear teeth clean and dry. If backlash exceeds .004", new gears should be used.
4. Gear and coupling splines should be a press fit on rotor shaft splines. New rotors and gears should be used if this spline fit is not tight.

Fig. 30 Dimensions for wood block to assemble supercharger. H and NH engines

Fig. 31 Pressing rotor on gear end plate. H and NH supercharger

Fig. 32 Bearing retainers and temporary assembly spacers. H and NH supercharger

5. Bearing spacers should be replaced if the outside diameter is visibly worn or grooved.
6. Drive rotor shaft ends should be checked for runout. Mount rotor and shaft assembly on the bearing journals and indicate the outside diameter of the splines at the shaft ends. Runout should not exceed .001" total indicator reading.
7. If the coupling drive pins or bushings show wear, press them out and replace with new pins and bushings in both the engine and supercharger halves.
8. Broken piston seals or rings must be replaced.

Supercharger, Assemble

1. Use a block of wood to hold the rotors for preliminary assembly and for checking end clearance, Fig. 30.
2. Soak new seals in lubricating oil and assemble in the two end plates with the sealing lip pointing away from the rotors.
3. Assemble the oil seals in the gear cover and bearing cover with the sealing lip pointing toward the rotors.
4. Assemble piston rings in rotor shaft grooves. Piston ring seals are used in superchargers after Serial No. 20,000.
5. Assemble rotors in wood block, Fig. 30, with gear ends up.
6. Assemble a bearing spacer to each rotor shaft and assemble end plate to rotor shafts, Fig. 31.
7. Assemble new double row ball bearings to rotor shafts with the bearing name to the outside. Drive bearings into end plate bearing pockets using special driving mandrel.
8. Assemble bearing retainers to end plate with lockwashers and flat head screws.
9. Assemble each rotor into proper bearings in gear end plate.
10. To check end clearance between rotors and end plate, use temporary spacers on the shafts and tighten in place with the shaft lock nuts, Fig. 32. Position the rotor holes so they lock against each other while tightening lock nuts.
11. With a feeler gauge check the clearance between rotors and end plate, Fig. 33. This clearance should be .005 to .006". Bearing spacers or steel shims are available in steps of .002", .003" and .005". The proper spacer or shims should be used between the shaft shoulder and bearing inner race.
12. On superchargers before Serial No. 20,000, assemble rotors and end plate to housing. With new oil seals in place, assemble plain end plate to housing. Assemble new roller bearings in the end plate with the name to the outside. With feeler gauges inserted through the inlet and outlet ports, check the clearance between the rotor lobes and housing bore, Fig. 34. Check the plain end plate clearance as shown in Fig. 35, which should be .007" minimum. If these clearances cannot be obtained, the supercharger should be returned to the factory for reconditioning.

Fig. 33 Gear end plate clearance. H and NH supercharger

Fig. 34 Minimum clearance on superchargers before serial number 20,000. H and NH supercharger

Fig. 35 Plain end plate clearance on superchargers before serial number 20,000. H and NH engines

13. On superchargers after Serial No. 20,000, separate inner races from new roller bearings and drive inner races on plain end of rotor shafts. Assemble rotors, end plate and gears to housing. Assemble plain end plate to housing. Install roller bearing outer races with rollers in end plate with name to outside.
14. On all units, remove temporary assembly spacers, Fig. 32, and install timing gear on drive rotor shaft. Install gear on drive shaft.
15. With rotors set at 90° apart, press on idler gear. Make certain that the rotors are timed correctly and that the two gears are meshing properly as the idler gear is being pressed on the shaft.
16. Lock the rotors with the special shaft locking wrench and install the idler gear lockwasher and lock nut.
17. Install the oil metering plunger and spring in the gear cover. The small hole in the plunger must be clean. The slots in the plunger must be lined up with the prongs on the spring retainer fitting or the cover will not pull up against the end plate.
18. With a new oil seal in place, install the cover to the end plate with a new gasket.
19. Support the assembly on the drive rotor shaft on the plain end and press the drive coupling on the shaft. Apply pressure on the coupling shaft, not the drive pins. With the special locking wrench in place on the drive coupling, install the shaft lockwasher and lock nut.
20. Install idler rotor shaft lockwasher and nut.
21. Assemble the bearing cover with a new oil seal and gasket.
22. Press generator drive sprocket on shaft and lock with washer and nut.
23. Install oil metering pin, spring and fitting in bearing cover. The radius of the metering pin must correspond to the radius of the coupling hub. It must work freely, and the hole in the metering pin must be clean and line up with the slot in the hub.
24. Install oil drain fitting in gear cover. Turn drive coupling by hand to see that rotors rotate freely.
25. After installing supercharger to engine, remove oil filler plug from top of gear end plate and add one quart of engine lubricating oil. Replace filler plug.

TURBOCHARGER

Under normal operating conditions, the turbocharger, Fig. 36, is subject to very little wear since the rotor is the only moving part. The rotor must be delicately balanced due to its high rotative speed and the extremely close running clearances. It is very important that this balance not be disturbed, and the running clearances must be maintained.

When it becomes necessary to dismantle the rotor assembly and to replace bearings and oil seals, or for any mechanical failure, the turbocharger must

be returned to the factory for overhaul. This is required since special equipment is needed to assure proper reassembly and balance.

Cleaning Procedure

The blower end of the supercharger should be cleaned after 4000 to 8000 gallons fuel consumption. *In the following procedure, numbers in parentheses refer to item numbers in Fig. 36.*

1. With intake and discharge ports covered, wash exterior of turbocharger thoroughly. Do not use a solution that will damage the finished surfaces.
2. Loosen and remove eight capscrews (17) and four lock plates (16) and take off compressor cover (12).
3. Use Bendix cleaner or some similar solvent, but *never* use a caustic solution or some other type that may attack aluminum as this will either weaken the compressor wheel or destroy its balance. Never use a wire brush or scraper; a brush with nylon or hog bristles is preferable.
4. If the unit is found to be very dirty when the compressor cover is removed, immerse the compressor wheel end of the turbocharger in the cleaning fluid up to the edge of the compressor housing (13) and allow it to soak. Use care not to rest the weight of the turbocharger on the compressor wheel or on the end of the shaft.
5. Dry the unit thoroughly with compressed air. Assemble the compressor cover to the turbocharger.

Checking Bearing Clearances

Fasten a dial indicator to the blower inlet casing flange and register it on a flat of the impeller nut or on a lathe center. Then by moving the impeller end of the shaft up and down, note the total indicator reading. If the total indicator reading exceeds .005″ the blower end bearing requires replacement.

The turbine end bearing can be checked by fastening the dial indicator to the turbine housing and register on the hub of the expander wheel or lathe center. Then by forcing the expander end of the shaft up and down, or sideways, make note of the total indicator reading. If the total indicator reading exceeds .005″ the bearing must be replaced.

GENERAL ENGINE SPECIFICATIONS

ENGINE IDENTIFICATION—Diamond T Service Parts Identification Plate is located inside of truck cab. Stamped on the plate is the model of the engine, transmission, auxiliary transmission, rear axle and front axle. This data represents only the equipment on the vehicle when it was shipped from the factory. Prior to Diamond T's assimilation by The White Motor Company, identification plates were attached to the engines and transmissions.

① 105 lb. ft. for ½″ nut, 135 lb. ft. for 9/16″ nut.
② Front and intermediate 70 lb. ft., center and rear 60 lb. ft.
③ Pistons removed from above.
④ For ½″ 90 lb. ft., for 9/16″ 105 lb. ft.
⑤ Piston is fitted so that it supports its own weight in any portion of the cylinder with all parts clean and dry.
⑥ No gap on U-Flex rings—ends butt.
⑦ No. 6 cylinder .004″.

Engine Section

CYLINDER HEAD, REPLACE

All Engines

When removing a cylinder head, a chisel or screw driver should never be used to pry it loose from the cylinder block. Use an eyebolt in the third or fourth spark plug hole, lifting up on the eyebolt while tapping lightly around the edges of the head with a lead or rawhide hammer or mallet. Be sure that all the head stud nuts or bolts have been removed before starting to remove the head.

Fig. 1 Cylinder head tightening sequence. Continental engines

In replacing the head, the stud nuts or bolts at the center of the head should be tightened first and then work outward from side to side and to the ends, Figs. 1 to 5.

Draw the nuts or bolts down evenly until all are normally tight. Then after the engine has run long enough to warm it up, make a final tightening with a torque wrench to the torque loads given in the *Tune Up & Valve Specifications* table.

Fig. 2 Cylinder head tightening sequence. XL engines

On overhead valve engines, be sure to check the valve clearances after the final tightening.

ROCKER ARM SERVICE

Overhead Valve Engines

Sludge and gum formation in the rocker arms and shafts will restrict the normal flow of oil to the rocker arms and valves. Each time the rocker arm and shaft assemblies are removed, they should be disassembled and thoroughly cleaned.

When disassembling rocker arms, place all parts on the work bench in their proper sequence to insure correct assembly.

Clean all gum and sludge formation from the inside and outside of the shafts. Clean oil holes and passages in the rocker arms and shafts. Clean the oil connector. Inspect the shafts for wear.

Check the ball ends of the rocker arms to be sure they are not pitted or rough. If used in this condition, it will be difficult to maintain valve clearances.

Service Note, XL Engines

Note that the third bolt from the rear on the left side of the cylinder head is drilled with an oil hole which supplies oil to the rocker arms. Fig. 6 shows the rocker arm assembly on these engines.

VALVES, ADJUST

All Engines

Adjust the valves to the clearances given in the *Tune Up & Valve Specifications* table. If the valves are to be adjusted warm, run the engine for about 30 minutes to normalize the expansion of all parts.

On overhead valve engines, be sure the cylinder head is properly tightened down before adjusting valve clearances.

VALVES, REMOVE

L-Head Engines

After taking off the cylinder head, remove the valve chamber covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Fig. 3 Cylinder head tightening sequence. Nash DT-252 engine

Fig. 4 Cylinder head tightening sequence. Reo 6 cyl. engines

Fig. 5 Cylinder head tightening sequence. Reo V8 engines

Fig. 6 Rocker arm assembly. XL engines

Remove all valves and place them in a board with numbered holes so that they can be identified as to the valve port from which they were removed.

Overhead Valve Engines

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

VALVES, GRIND

All Engines

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum amount of metal required to clean up the valve faces. If the outer

edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}$", otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the block or head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing has a valve guide pilot.

The valve seat width after refacing should be $\frac{5}{64}$" to $\frac{7}{64}$" on the intake. The width of exhaust seats should be $\frac{7}{64}$", Fig. 7.

A simple check can be made to prove the fit of the valve in the valve seat by spreading a thin film of Prussian Blue on the valve face and inserting the valve in the valve seat. With hand pressure, rotate the valve ¼ turn, remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer will indicate an inaccurate valve and valve seat operation.

Fig. 7 Valve seat width recommendations

VALVE ROTATORS

Continental, Hercules, Reo & XL Engines

The parts involved in the rotating mechanism are a special spring seat retainer, a pair of flat half-moon keys, a close fitting cap located on the valve stem and a specially constructed valve stem, Fig. 8.

In order to accommodate valve expansion, the valve lash must be maintained. When camshaft rotation causes this lash or clearance to be taken up, the cap on the valve stem causes the valve keys to lower the spring retainer, removing the load of the valve springs from the valve *before* the valve is raised from its seat. A clearance of .002-.006" should be maintained between the end face of the valve stem and cap. This is the distance the spring retainer is lowered *before* the valve is moved. The slow valve rotating motion is caused by the vibration of the valve, the flowing of exhaust gases around the valve head, and a slight rotating motion imparted to the valve by the valve spring.

Whenever valve work is done, check the clearance, using the special gauge shown in Fig. 9. If there is no clearance, grind off the end of the valve stem. If the clearance is too great, grind off the open end of the valve cap.

If the special gauge is not available, a check for clearance can be made by holding the assembled valve and rotating mechanism in the hands. With one hand, press down on the valve cap and turn the valve with the other hand. If the valve turns readily, at least it indicates that there is some clearance present.

Fig. 8 Rotating exhaust valve mechanism. Continental, Hercules, Reo and XL engines

Fig. 9 Using special gauge for checking clearance between valve stem and valve stem cap on engines with exhaust valve rotators

VALVE SEAT INSERTS

Continental, Reo & XL Engines

Since these inserts are too hard to reface by the ordinary hand grinding method, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and the valve guide pilot is a snug fit in order to assure a concentric finish. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert (if a suitable puller is not available), drill two holes at opposite sides of the insert but not all the way through. Then cut out the undrilled portion with a sharp chisel and remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the new insert with "dry ice" to obtain maximum contraction of the metal and place it in the recess. If necessary, the insert may be pounded in by using a round driver the same size as the insert and pounding on same with a hammer.

If a standard insert is too loose, secure an oversize insert. Of course, the recess should be bored out to accommodate the oversize insert.

When installed, peen the block or head around the insert bore to insure the insert remains in place, Fig. 10.

Fig. 10 Magnified view showing how cylinder head or block should be peened to secure valve seat insert in place

VALVE SPRINGS

After removing the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. If not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Tune Up & Valve Specifications* table within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should be scrapped.

Fig. 11 Valve lifter and guide construction. XL engines

VALVE GUIDES, REPLACE

Clean the valve guides with a wire guide brush and check the clearance between valve stems and guides. Excessive clearance will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Valve stem-to-guide clearance may be checked with a dial indicator or a suitable plug gauge. Lacking either of these tools, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check indicates excessive clearance, it will be necessary to replace the valve guide.

If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

Valve guides may be removed and installed with a suitable puller and installer made for the purpose. If such equipment is not available, the old guides can be driven out or they can be pulled out by using a piece of pipe together with a long bolt and suitable washers.

After the new guides have been installed, they should be reamed to round out the holes and to provide adequate operating clearances.

VALVE LIFTERS

Continental Engines

Valve lifters are of the mushroom type carried in guide clusters bolted to the cylinder block. When worn, it is usually easier to replace the entire lifter and cluster unit rather than try to use old lifters with new brackets and vice versa.

Hercules Engines

On JX and QX engines, valve lifters are of the mushroom type, operating in bushings pressed in the block. To remove the lifters it is necessary to remove the camshaft. The old bushings may then be pressed out and new ones installed. The bushings should then be reamed to provide proper operating clearance.

Reo Engines

These engines are equipped with barrel type lifters which can be lifted out from above after taking out the push rods. With this construction the oil pan and camshaft need not be disturbed.

XL Engines

Lifters in these engines are of the mushroom type operating in guide holes bored in the cylinder block. To remove lifters, therefore, it is necessary to take out the camshaft and remove the lifters through the bottom of the engine.

As shown in Fig. 11, the valve lifter bores have spring-loaded retainers in the block, which are used to hold up the lifters when pulling out the camshaft. When the lifter is pushed up, the retainer snaps into the groove at the top of the lifter. After the camshaft is installed, the lifters may be pushed down into position by the push rods.

Nash DT-252 Engine

Mushroom type lifters, operating in guide holes bored in the block, make it necessary to remove the camshaft when it becomes necessary to replace lifters.

TIMING GEARS

Continental & XL Engines

For correct valve timing, timing gears should be assembled as shown in Figs. 12 and 13. Always use suitable puller and pusher equipment when servicing gears. This is particularly important in the case of the camshaft gear as there is danger of loosening the welch plug in back of the camshaft if the gear is driven on with hammer blows.

Hercules Engines

Camshaft Gear—The camshaft must be removed in order to install a new camshaft gear. This is done by removing the gear cover, crankshaft oil slinger, oil pan and, on engines where the oil pump is driven from the center of the camshaft, take off the oil pump. Remove the valves and raise the lifters so they will not interfere with the camshaft as it is being withdrawn.

On QXLD engines, the camshaft gear can be pressed on from the rear against the flange on the front of the shaft.

On all engines, valve timing is correct when the marked teeth are meshed.

Crankshaft Gear—Since the crankshaft gear will very likely become damaged when removed, a new one should be installed. When doing so, heat the gear in boiling water to obtain maximum expansion of the metal and coat the shaft

Fig. 12 Valve timing. Continental engines

with white lead to make assembly easier. For correct valve timing, match the marked tooth of the crankshaft gear with the marked tooth of the camshaft gear.

Idler Gear—The idler gear may easily be removed by pulling it forward out of the case. However, on JX and QX engines, the gear can only be pressed on from the rear against the flange on the front of the shaft.

Gear Cover—The outside of the crankshaft and the boss of the gear cover (and oil pan on some engines) must have sufficient clearance to permit a .010" feeler gauge (approximately) to be inserted at all points. If the cover rubs against the crankshaft at any point, an oil leak may result. This can be corrected by either shifting the gear cover enough to eliminate the rub or by filing the gear cover boss to obtain sufficient clearance.

Reo Engines

Valve timing is correct when the timing gears are installed so that the timing marks on the gears are meshed. Fig. 14 illustrates the relationship of the parts on V8 engines.

Fig. 13 Valve timing. XL engines

TIMING CHAIN

Nash DT-252 Engine

When installing a new chain, assemble it over the sprockets so that when the camshaft sprocket is bolted to its hub, the timing marks on both sprockets are opposite each other and in line with the centerline of both the camshaft and crankshaft.

CAMSHAFT & BEARINGS

Continental & XL Engines

Camshaft end play is controlled by a thrust plate behind the camshaft gear. End play should be held to about .005″ and can be checked by forcing the camshaft back to the limit of its travel and inserting a feeler gauge between the thrust plate and the front end of the camshaft. If clearance is excessive, install a new thrust plate.

Camshaft bearings should be installed in sets and care must be exercised to see that the oil holes in the bearings and the oil feed holes in the block are aligned to insure adequate lubrication.

After installing the bearings, they should be line-bored to round out the holes and to provide a running clearance of .0015-.0025″.

Hercules Engines

On all engines, camshaft end thrust is controlled by a special screw through the gear cover, Fig. 15. At long intervals or when the engine has been disassembled for repairs, the end play should be checked. If an adjustment is required, loosen the lock nut and tighten the screw until the fibre plug at its inner end contacts the steel plug in the front end of the camshaft. Then back off the screw ⅛ turn and tighten the lock nut. (The idler and accessory shaft adjustment is made in the same manner.)

On engines having the cylinder block separate from the crankcase, any reaming of camshaft bearings should be done after the block is bolted to the crankcase to assure proper camshaft fit.

Nash DT-252 Engine

Camshaft end thrust is controlled by flanges on the front bearing. If end play becomes excessive, remove the old bearing and install a new one.

When necessary to install camshaft bearings due to wear, they should be pressed in place and reamed to round out the holes and to provide adequate running clearance.

Reo Engines

Camshaft end play is controlled by a thrust plate just behind the camshaft gear. End play should be held to about .005″ and can be checked by forcing the shaft back to the limit of its end play and inserting a feeler gauge between the thrust plate and the front end of the shaft. If end play is excessive, install a new thrust plate.

On these engines, steel-backed, lead babbitt-lined split bearings are used.

Fig. 14 Relationship of timing gears and related parts. Reo V8 engines

PISTONS & RODS, REMOVE

All Engines

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Before removing pistons, mark the pistons with a file on the inside of the skirt to indicate the bore from which each piston was removed and also its position in the bore with relation to the camshaft side of the engine. Connecting rods should also be suitably marked if they are not marked already.

Remove the connecting rod caps and push the assemblies out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. It is advisable to install caps on rods as they are removed to avoid mixing parts.

Fig. 15 Arrows indicate adjusting screws which control end play of camshaft, idler shaft and accessory shaft. Hercules JX and QX engines

PISTONS & RODS, ASSEMBLE

All Engines

If the pistons and rods have factory markings to indicate their position in the cylinders, assemble and install them according to these marks, or according to the marks made during removal if they were not otherwise marked, Fig. 16.

Fig. 16 Correct assembly of pistons and rods. Reo V8 engines

Fig. 17 Removing cylinder sleeve. XL engines

CYLINDER SLEEVES

XL Engines

Cylinder sleeves or liners used in these engines are of the dry type and can be removed and installed with the equipment shown in Figs. 17 and 18.

These sleeves may be rehoned to take .005″ and .010″ oversize pistons. If necessary to exceed .010″ oversize, a new sleeve and piston should be installed.

To remove a sleeve of this type, use the puller equipment as shown in Fig. 17. Make sure the shoe is square under the sleeve and that the entire assembly is centered on the sleeve to be removed. Tighten the nut to pull the sleeve out of the block. Note the size marked on the outside of the sleeve and replace with the same size.

Before installing the new sleeve, thoroughly clean the bore in the block as well as the outside of the sleeve, especially under the top flange. Then coat the outside of the sleeve with a light mixture of white lead and oil to make installation easier.

Place the sleeve in the bore and pass the shoe and screw down through the sleeve, bringing the shoe to rest against the wall of the cylinder bore, Fig. 18. Turn the shoe on an angle so as to obtain maximum bearing. Place the pressure plate squarely on top of the sleeve and turn the nut down to the plate.

Start the sleeve into the bore by hand pressure on the nut. Then after the sleeve is started into the bore, turn the nut with a wrench, continuing with care until the sleeve is almost in its final position. Release the nut slightly and check to see that the shoe has not slipped and is still well supported on the cylinder boss. See that the flange is clean and then tighten the nut to draw the sleeve into its final position.

After the sleeve is installed, it should be honed to round out the hole and to size it properly for the piston to be used.

It is important that refinished cylinder bores are trued up to have not more than .0005″ out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at room temperature (70°) when the piston is checked for fit in the bore. Therefore, the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10° between the temperature of parts is sufficient to produce a variation of .0005″.

With the piston rings and pins removed, and cylinder wall and piston dry and clean, insert the piston upside down in the bore. Use a feeler ½″ wide which is long enough to extend the full length of the piston. The thickness of the feeler should be the same as the clearance given in the *Pistons, Rings & Bearings* table. With the feeler hooked to a spring scale, a pull of 5 to 10 lbs. should be required to pull the feeler past the piston.

Reo Engines

Cylinder blocks are equipped with wet type cylinder sleeves. Each sleeve is sealed by the cylinder head and head gasket at the top, while rubber packing rings are fitted in a recessed groove in the bottom to keep the lower end water tight and permit the required expansion.

Special sleeve pullers are commercially available, and after the sleeve is pulled and the rubber ring removed, clean the ring grooves. The shoulders on the new sleeve and in the block should also be cleaned. Always use new rubber packing ring, and apply a thin film of hydraulic brake fluid, castor oil or a thick soap solution around the lower end of the sleeve to make installation easier.

When installing the sleeve, note when the end enters the rubber packing. Then push the sleeve down in place so that its top shoulder seats in the corresponding shoulder in the block. The final position of the sleeve is when it protrudes .001-.003″ above the top surface of the block.

PISTONS, REPLACE

All Engines

Before a honing or boring operation is started, measure all new pistons with a micrometer at points 90° away from the piston pin. Then select the smallest piston for the first fitting. The slight variations usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

Fig. 18 Installing cylinder sleeve. XL engines

PISTON RINGS, REPLACE

All Engines

When new rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the diameter of the bore. This is done with a "Glazebuster" or a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is to be fitted. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the

steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

PISTON PINS, REPLACE

All Engines

Pins should be selected that can be installed by pushing with the palm of the hand with the piston at normal room temperature. To make assembly easier, however, heat the piston in boiling water for a few minutes to obtain maximum expansion of the metal and quickly insert the pin.

ROD BEARINGS, REPLACE

All Engines

Rod bearings consist of two half shells. When the bearings are placed in the rod and cap the ends extend slightly beyond the parting faces so that when the rod bolts are tightened, the bearings will be clamped tightly in place to insure positive seating and prevent turning. *The ends of these bearings should never be filed flush with the parting surface of the rod and cap for the above reasons.*

Service bearings are provided in standard sizes and several undersizes, including undersizes for reground crankshafts.

After installing new bearings, the oil clearance may be checked with Plastigage which is readily available at any auto parts jobber. Full instructions for its use are furnished with the envelope in which it is contained.

MAIN BEARINGS, REPLACE

All Engines

Main bearings are of the insert type, requiring no reaming or scraping. They may be removed and replaced without removing the crankshaft.

Plastigage may be used to check bearing clearance and instructions for its use are contained in the package.

CRANKSHAFT END PLAY, ADJUST

Continental Engines

Crankshaft end thrust is controlled by flanges on the front main bearing. Whenever end play becomes noticeably excessive, it should be immediately adjusted, otherwise damage to the front main bearing will result.

End play of the crankshaft is regulated by a removable collar just to the rear of the crankshaft timing gear. There is a shim pack between this thrust collar and the front main bearing. Excessive clearance may be reduced by removing the right number of shims. Take the timing gear off the crankshaft and remove enough shims to reduce the end play to the recommended limits of .005″ to .008″.

Fig. 19 Oil pump mounting. Nash DT-252 engine

Hercules, Nash & XL Engines

Crankshaft end thrust is controlled by flanges on the rear main bearing on Hercules and XL engines, and on the center main bearing on Nash engines. Whenever new bearings are fitted, check the end play carefully by forcing the crankshaft to the limit of its end play and measure the clearance with a feeler gauge between the bearing flange and the crankshaft cheek. If end play is excessive, install a new flanged bearing.

On Nash engines, end play limits are .003-.007″. On Hercules engines, end play should not exceed .005″, and on XL engines, end play limits are .004-.012″.

Reo 6 Cyl. Engines

End thrust is taken by two thrust plates at the front main bearing and is adjusted by shims located at the rear of the crankshaft timing gear.

Reo V8 Engines

Crankshaft end thrust is controlled by flanges on the rear main bearing and should be held to .004-.008″ end play.

CRANKSHAFT OIL SEAL, REPLACE

Reo V8 Engines

Oil sealing at the rear main bearing is controlled by a wick-type seal in the same manner as for Continental engines above.

Reo 6 Cyl. Engines

On these engines, the rear crankshaft oil seal is of neoprene material and spring loaded, assembled in a one-piece steel stamping. It is only furnished and replaced as an assembly.

The seal contacts around the rear crankshaft hub and is positioned by two dowels in the crankcase. The upper half is secured to the crankcase by four capscrews and the lower half by five socket type capscrews to the rear arch type oil pan support. These five capscrews are screwed through the oil seal housing from the inside of the arch while the four upper capscrews are screwed through the oil seal housing from the flywheel side.

To replace the oil seal, the flywheel and oil pan must be removed.

XL Engines

Crankshaft rear bearing oil seal consists of two pieces of special packing. One piece is installed in the groove in the rear bearing cap and the other piece is installed in a similar groove in the cylinder block.

Position the rear bearing seal in the groove in the cylinder block. Lay an improvised mandrel in the bearing bore and strike the mandrel with a hammer to drive the seal into the groove. Install the seal in the bearing cap in a similar man-

Fig. 20 Water pump. Continental engines

Fig. 21 Water pump. XL engines

ner. Using a sharp knife, cut off both ends of each seal which project out of the grooves. When cutting off the ends of the seals, do not leave frayed ends which would prevent proper seating of the bearing cap if the ends should extend between cap and cylinder block.

Nash DT-252 Engine

The threaded oil return has a steel-backed rubber seal. The seal is in halves and fits closely over the edge of the rear bearing oil return groove. It bears firmly on the smooth area of the crankshaft.

OIL PUMP REPAIRS

All Engines (Except Reo)

Conventional gear type oil pumps, located in the crankcase, are used on all engines. After removing the oil pan, the pump may be unfastened from its mounting and disassembled for repairs.

Inspect the pump gears for nicks or burrs. Inspect the bottom cover for wear and dress it down on a surface plate with emery if necessary. Place the cover on the pump and check the drive shaft end play. If end play is in excess of .006", replace the drive and idler gears.

Service Note, XL Engines

Whenever the oil pump is removed from these engines, the distributor will have to be taken off as well in order to reinstall the pump without damage. The reason for this is that the slot in the end of the oil pump drive shaft must match the tang on the end of the distributor drive shaft. If an attempt is made to install the oil pump with the distributor in place, it will be difficult or impossible to align the slot and tang with the result that the pump will be damaged when its mounting bolts are tightened.

Be sure to retime the ignition when the oil pump and distributor have been reinstalled.

Service Note, Nash Engines

On these engines, the oil pump drive gear which meshes with the camshaft gear is splined to the top end of the oil pump shaft, Fig. 19. The spline is a free fit so that it may be removed from below after the oil pump is dropped. The oil pump drive gear is installed from above after the distributor bracket and gear have been removed.

Reo Engines

Oil pump is of the rotary type and is assembled to a special machined boss inside the crankcase. As the two rotors are matched at the time of assembly a complete new unit must be installed as rotor repairs are never satisfactory.

Oil pump drive gear is driven from the gear on the camshaft. The gear is pinned to the pump shaft and is replaceable.

WATER PUMP REPAIRS

Continental, Reo & XL Engines

The water pumps used on these engines are of the ball bearing type with sealing accomplished by a non-adjustable spring-loaded seal, Figs. 20 and 21. In servicing these pumps, note carefully the arrangement of the seal parts as they are removed so that the new seal may be assembled correctly.

After disassembly, inspect the face of the pump body against which the sealing washer turns. Reface this surface if it is scored. Discard the pump impeller if it is corroded or loose on the shaft.

Nash DT-252 Engine

A "packless" sealed type water pump is used on these engines. The seal is of "cartridge" construction, installed and serviced as a unit. The sealing member is enclosed in a metal cartridge which is mounted and sealed in the pump body by means of a flexible rubber ring. The sealing member is pressed against the shaft by constant spring pressure exerted through the bushings. The spring chamber also acts as a reservoir for lubricant. A view of this pump can be seen in the Nash engine illustration.

Hercules Engines

The water pumps used are of the packless type, engine driven through a gear or belt drive. Water sealing is accomplished with a spring-loaded seal which is not adjustable but must be replaced in the event of a leak.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set

Fig. 22 Ignition details. Reo V8 engines

Fig. 23 Zenith Series 28 carburetor. Used on Continental Series K and T-6427 engines as well as Hercules TDXB

Fig. 25 Zenith 29 Series carburetor. Used on Continental R-6572 engine

Fig. 24 Float setting. Zenith 28 and 63 Series carburetors

Fig. 27 Zenith 63 Series carburetor

Fig. 26 Float setting. Zenith 29 Series carburetor

according to specifications.

2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

CARBURETOR, ADJUST ZENITH 28ADA-10

This carburetor, Fig. 23, is a down-

draft, single-barrel unit with a mechanically-operated accelerating pump and a manifold vacuum controlled power jet system.

Float Setting

Float height setting is measured from the gasket surface or parting line of the float chamber cover to the bottom of the float at the center, Fig. 24, with the fuel inlet valve seated (holding float chamber cover upside down). This distance should measure 1½".

Under three pounds fuel pump pressure the fuel level should measure $\frac{25}{32}$".

Idle Mixture

For a preliminary adjustment, turn the idle adjusting needle into its seat and open one full turn. Run the engine until it reaches normal operating temperature and alter the adjustment as required to obtain smooth performance. The range should be between 1 and 1½ turns open.

Accelerator Pump

The accelerating jet and the pump spring control the rate of acceleration discharge. The stroke of the pump is controlled by the position of the pump rod in relation to the pump piston rod. The stroke can be varied by changing the position of the hairpin clip on the pump piston rod. The upper groove allows a half stroke. The center groove allows an intermediate or ¾ stroke and the lower groove allows maximum or full stroke.

ZENITH 29D-13

This carburetor, Fig. 25, is a downdraft carburetor with a concentric float bowl. This design assists in the proper metering of the air and fuel to the engine without flooding when the vehicle is operated at extreme angles. The fuel chamber can be tipped at an angle to any position within a circle up to 45°. This feature is very helpful when the vehicle is operated in hilly country, in and out of excavations, on ramps, or when operated at side angles.

Float Setting

With the cover and float assembly held upside down and fuel inlet needle held closed, the distance indicated at "A" in Fig. 26 should be $1\frac{41}{64}$".

Idle Mixture

For a preliminary adjustment, turn the needle into its seat and open one full turn. Run the engine until it reaches normal operating temperature and alter the adjustment as required to obtain smooth performance. The range should be 1 to 1½ turns open.

ZENITH 63 SERIES

Zenith 63AW-10 and 63AW-12 model carburetors are used on Hercules engines, Fig. 27. They are single-barrel, updraft carburetors with a manifold vacuum controlled power and accelerating system. A removable venturi tube measures the volume of air which passes through the carburetor.

Float Setting

This adjustment is made in the same manner outlined for 28 Series carburetors. The distance "A", Fig. 24, should be $1\frac{13}{32}$". Under three pounds fuel pump pressure the fuel level should measure $\frac{55}{64}$".

Idle Mixture & Pump Adjustment

These adjustments are made in the same manner outlined for 28 Series carburetors.

HOLLEY AA-1G & 852-FFG

These carburetors, used on XL engines, are dual downdraft units incorporating an integral governor. The governor throttle mechanism is part of the carburetor and has been designed to provide the needed power required for moving the throttle to governing speeds as controlled by a separately driven governor rotor. The combination of these two units give instant response and accurate governing.

The carburetor and governor can be cleaned and serviced with ordinary tools and the governor rotor can be serviced independent of the carburetor. *Do not under any circumstances apply compressed air to an assembled carburetor as to do so may rupture the governor diaphragm.*

Fuel & Float Level

When checking the fuel level in an open vessel, under 3 lbs. pump pressure the level should measure $\frac{19}{32}$" on AA-1G models and ⅝" on 852-FFG units. The measurement is taken below the surface of the float chamber cover (gasket in place) to the level of the fuel. The level may be corrected by bending the float arm, Fig. 28.

The float level can be set when the air horn is off by gauging the distance between the bottom of the float and the flange surface of the air horn, Fig. 29. Holding the air horn upside down and the float in the closed position, measure the distance from the flange surface of the air horn to what would normally be the bottom side of the float (not the soldered seam). The correct distance should measure 1¼". Bend the float lever arm as required to correct the float level.

Idle Mixture

The idle mixture is controlled by the idle adjustment needles. Turning these needles in makes a leaner mixture and turning them out makes the mixture richer. Turn the needles in until they just touch the seats and back off one full turn.

When the engine has warmed up to operating temperature, alter the adjustment as required to obtain smooth performance. The range should be between 1 and 1½ turns.

Accelerating Pump

The quantity of the fuel discharged by the accelerating pump can be controlled by changing the position of the pump link in the throttle lever. Of the three different positions (marked 1, 2 and 3) number 2 is the average setting, number 1 is for summer and 3 is for winter operation.

HOLLEY 885-FFG

Used on XL engines, this unit is a dual concentric carburetor with all metering jets and passages grouped together and located in the center of the float bowl. The float bowl is a separate unit, being suspended inside the main body from the main body cover. With this design the fuel is kept cool by circulation of the main air supply around and under the float bowl.

Fuel & Float Level

The fuel level can be accurately set by gauging the distance between the bottom of the floats and the chamber cover surface. When setting the float level it is important that both the open and closed positions be checked.

To gauge the closed position of the floats, hold the float chamber cover upside down and measure the distance from the float chamber gasket to what would normally be the bottom side of the free end of the floats. The distance should measure $\frac{5}{32}$" with the fuel inlet valve closed. Correction can be made by bending the float lever arms up or down as required.

The open position is gauged by raising the floats up until the float stop arm comes to rest against the inlet needle seat housing. The floats should bottom in the bowl. If necessary, correction can be made by bending the stop arm on the float lever.

Idle Mixture

As an initial adjustment, the idle needles should be screwed in until they just touch the seat then backed out from ½ to 1 turn. After the engine has been run long enough to warm it up, alter the adjustment as required to obtain smooth performance.

Accelerating Pump

The accelerating pump is provided with an adjustment for varying the quantity of accelerating charge. This adjustment is made by changing the position of the pump link in the holes provided in the throttle lever. The position furthest away from the throttle shaft is the cold weather setting since it gives the longest stroke thereby the greatest discharge. The middle position is the average setting, and the position nearest the pivot is used under conditions of very hot weather.

CARTER YH-895SA

Used on Nash DT-252 engine, this unit is of conventional Carter design with the circuits arranged in a hori-

Fig. 28 Holley AA-1G carburetor. Typical of 852-FFG. Used on XL engines

Fig. 29 Float setting. Holley AA-1G and 852-FFG carburetors

Fig. 31 Carter YH float circuit. Nash DT-252 engine

Fig. 33 Carter YH pump circuit. Nash DT-252 engine

Fig. 34 Carter YH choke circuit. Nash DT-252 engine

zontal or side draft position. See Figs. 31 to 34 for details of construction.

Float Setting

With the gasket removed, bowl cover assembly inverted and float resting on seated needle, the distance from the bowl cover to the top of the float should be ⅜". Do not depress the float lip against the spring-loaded pin in the needle but let the float rest of its own weight. Adjust by bending the float lever arm, Fig. 31. Check the float setting with the bowl cover held at eye height in a level position.

Metering Rod Setting

This adjustment is important and must be checked each time the carburetor is reassembled or a lean metering rod is installed.

With throttle valve seated in bore of carburetor, press down on the upper end of the diaphragm shaft, Fig. 32, until the diaphragm bottoms in the bowl. The metering rod must contact the bottom of the metering rod well and the metering rod arm must contact the lifter link between springs and at the supporting lug. Adjust by bending the lip up or down.

Accelerating Pump

If acceleration is not satisfactory, remove the pump housing, intake rivet plug and ball check, Fig. 33. Then remove discharge ball check and spring. Examine the diaphragm for wear or damage. Be sure intake check and discharge check are not clogged with lint or foreign matter. The intake and dis-

Fig. 32 Carter YH high speed circuit. Nash DT-252 engine (2 views)

Fig. 36 Holley 1174 governor as applied to AA-1G carburetor. Also used on 852-FFG and 885-FFG carburetors

Fig. 37 Holley 1174 governor showing vacuum adjustment

Fig. 35 Zenith carburetor governor adjustments

charge ball checks must seat, as a leak at these points will result in poor acceleration. Inspect and replace all worn parts, clean and blow out all passages with compressed air. *Pump jet is permanently installed, do not remove.*

Fast Idle Setting

With the thermostatic coil housing, gasket and baffle plate removed, Fig. 34, partially open throttle, close choke valve, and then close throttle valve. This will allow the fast idle cam to revolve to fast idle position.

With choke held tightly closed, there should be .030″ clearance between throttle valve and bore of carburetor (side opposite idle port). Adjust by bending the connector link at the angled portion.

Unloader Setting

This adjustment must be made after the fast idle adjustment, Fig. 34. Hold the throttle valve in wide open position and close choke valve as far as possible without forcing. There should now be ⅝″ clearance between lower edge of choke valve and wall of air horn. Adjust by bending choke shaft unloader arm.

Automatic Choke Setting

If the carburetor has a one-piece choke piston, set the choke cover one point lean. With a two-piece choke piston, set cover one point rich.

Idle Mixture

Turn the idle adjusting needle into its seat and back off 1 to 1½ turns. After the engine has warmed up, alter the adjustment as required to obtain smooth performance.

CARBURETOR GOVERNOR

Zenith

To change the governed speed, remove the seal wire and large seal plug, Fig. 35. Turn the main adjusting screw clockwise to increase or counter-clockwise to decrease governed speed. If the governor does not show definite response to changes of ¼ to one full turn of the adjusting screw, it indicates a defective governor.

If the governor "surges" or "hunts" to a higher or lower engine speed, remove the small seal plug and turn the compensating spring adjusting screw ¼ turn counter-clockwise until the surge is overcome.

If the governor does not respond quickly enough when governed speed is approached and the action "lags" or is "flat", turn the compensating adjusting screw clockwise until the symptom is overcome. Do not turn the adjustment more than ½ turn at a time without checking the performance of the vehicle on the road.

Holley Model 1174

Used with Holley carburetors, this governor, Fig. 36, is a vacuum controlled device featuring all the advantages of a mechanical governor without lengthy and complicated linkage. Should it become necessary to make any changes, proceed as follows:

To adjust the governor cut-off speed, remove the seal from the screw on the side of the governor housing and remove the screw. Rotate the engine until the end of the governor rotor, which carries the adjusting screw, is in line with the hole from which the screw was removed. Turn the adjusting screw clockwise to increase or counter-clockwise to decrease governed speed.

Whenever the governor has been disassembled and serviced, after reassembling turn the adjusting screw clockwise until it stops, then turn it counter-clockwise three full turns. Final adjustment is then made after the governor has been assembled to the engine.

The vacuum adjusting screw, Fig. 37, regulates the rpm spread between the governor full load cut-off speed and the no-load engine speed. Turning the screw clockwise will decrease the rpm spread. Turning it counter-clockwise will increase the spread. Changing the position of the screw will change the average governor speed and this should be corrected by the rotor adjusting screw.

Clutch, Transmission & Rear Axle

For Allison, Clark, Fuller, New Process, Spicer and Warner transmissions used on Diamond T trucks, see the "name" chapters for service procedures and lubricant capacities

For Eaton and Timken (Rockwell) driving axles used on Diamond T trucks, see the "name" chapters for service procedures and lubricant capacities

CLUTCHES

Make ①	Model ①

Borg & Beck	12E
Lipe-Rollway	14ML
Rockford	14TT
Rockford	15TT
Spicer	2 Plate

① Clutches may be identified by the manufacturer's number stamped on a name plate, or on the clutch cover, or on the flywheel ring on Lipe units.

BORG & BECK

These clutches, Fig. 1, are single plate, dry disc types with no internal provision for adjustment for wear. However, each release lever is adjusted individually to the correct height, and no attempt should be made to adjust these levers unless the clutch is to be dismantled for overhaul. Overhauling the clutch should not be attempted unless a clutch rebuilder is available. Lacking this equipment it is recommended that the clutch cover and pressure plate assembly be exchanged for a rebuilt unit.

Clutch Pedal, Adjust

The general procedure for adjusting the clutch pedal is to shift the pedal down away from the toe board until the clearance or free movement is 1 to 1½". The pedal pad should come in contact with the toe board when the pedal is pressed down. If it does not move that far, making it necessary to spring the pedal to make the pad touch the toe board, shift the pedal down a little more.

Press the pedal down and note the distance the release bearing travels after it comes in contact with the release levers. To obtain a clean release the levers should be pushed toward the flywheel $\frac{7}{16}$". If it does not travel this distance shift the pedal up, bearing in mind that the pedal pad must touch the toe board as above.

Clutch Assembly, Replace

After removing the transmission, but before removing the clutch, mark with a punch, the flywheel, clutch cover and pressure plate so that these parts may be assembled in their same relative positions and in the same position on the flywheel if the same clutch is to be reinstalled. This is important because they are balanced as an assembly.

Fig. 1 Typical Borg & Beck clutch

To remove the clutch, pull out the clutch release bearing and sleeve. Unfasten the clutch cover from the flywheel, loosening each cap screw a few turns in succession until the cover is free. The clutch assembly and driven disc can then be removed from the flywheel.

When installing the clutch, coat the pilot bearing in the end of the crankshaft with wheel bearing grease. Clean the surfaces of the flywheel and pressure plate, making certain no oil or grease remains on these parts. Hold the cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the pilot bearing in the crankshaft. Bolt the clutch cover loosely to the flywheel, being sure the punch marks previously made are lined up. To avoid distortion of the clutch cover, tighten the cover bolts a few turns each in progression until all are tight. Guide the transmission into place, using care to see that the driven disc is not bent. Use a floor jack to support the transmission so that the clutch shaft may be guided through the driven disc safely. Adjust the clutch pedal free travel.

LIPE-ROLLWAY TYPE ML

This clutch, Fig. 2, is a single plate, dry disc type in which pressure on the driven disc is provided by a heavy spiral spring acting through 20 interlocked levers.

Clutch Adjustment

The original setting of the clutch provides for 1½" free movement of the clutch pedal. As the facings wear, the clutch sleeve moves toward the clutch release bearing, reducing the clearance and automatically cutting down on the free travel of the clutch pedal. When this travel drops to about ½", the clutch should be readjusted.

Do not adjust the clutch pedal linkage until the clutch has been adjusted to the correct Dimension "A", Fig. 3. The correct Dimension "A" for the clutches used are as follows:

Clutch	Dimension "A"	Shims Req. ①
13ML	$1\frac{1}{16}$"	.015"
14ML	$1\frac{5}{16}$"	.015"
15ML	$1\frac{3}{16}$"	.015"

① Removal of one shim .015" thick is equivalent to reducing Dimension "A" by $\frac{3}{32}$". The number of shims listed for each clutch should be placed under each strap when overhauling the clutch.

1. To adjust the clutch, block the clutch pedal in the depressed position. This is important, otherwise the straps and studs may become bent.
2. Back off adjusting nuts five full turns.
3. Remove pedal block. This will allow the adjusting plate to move out of contact with the adjusting shims.
4. Remove a sufficient number of shims to obtain Dimension "A". It is usually sufficient to remove only one shim from each stud, Fig. 4, then checking Dimension "A" before removing more. *Be sure no portion of the shim is torn and remains under the flange of the adjusting plate and that an equal number of shims remain under each strap.*
5. Reblock the clutch pedal. This moves the adjusting plate into contact with the adjusting shims. Then tighten each adjusting strap nut firmly.
6. Recheck Dimension "A".
7. After the correct Dimension "A" has been established, adjust the vehicle clutch release linkage so as to obtain proper release bearing clearance of ⅛" to $\frac{5}{32}$", as indicated in Fig. 5.

Fig. 2 Lipe-Rollway Type ML clutch

Fig. 3 Adjusting points. Lipe-Rollway ML clutch

Clutch Driven Disc, Replace

1. After removing transmission, unfasten clutch from flywheel and remove clutch and driven disc.
2. Remove flywheel ring stud nuts and adjusting straps one at a time and place the correct number of shims (see table above) under each strap.
3. Examine flywheel, making sure friction face is clean, smooth and dry.
4. Check release bearing and pilot bearing to make sure they are in good condition. Both these bearings are factory sealed and require no further lubrication.
5. Install a new driven disc and bolt the clutch to the flywheel, using a spare splined shaft to align the disc. When bolting the flywheel, screw in each bolt until it just contacts the cover plate, then gradually tighten alternate bolts until the clutch is drawn up evenly against the flywheel. Tighten remaining clutch-to-flywheel bolts.
6. After clutch is installed, check for proper release. Adjust clutch and pedal linkage as outlined above.

Fig. 4 Removing shims for clutch adjustment. Lipe-Rollway ML clutch

Pressure Plate, Replace

A pressure plate dished in excess of .015″ or badly scored should be replaced with a new part. After removing the transmission and clutch from the flywheel, proceed as follows:

1. Place clutch on arbor press with pressure plate down and compress spring as far as possible.
2. Remove four retractor springs after first removing pins.
3. Slowly release arbor press, allowing clutch spring to return to normal position.
4. Holding clutch assembly together by hand, turn it over and carefully lift off pressure plate.
5. Install new pressure plate, turn clutch assembly over and compress in arbor press.
6. See that retractor springs are in place and install pins.
7. Remove clutch from press and reinstall on flywheel.

Fig. 5 Clearance between release bearing and release sleeve should be 1/8″ to 5/32″. Lipe-Rollway ML clutch

Fig. 6 Rockford Type TT clutch

ROCKFORD TYPE TT

This clutch, Fig. 6, is of the single plate dry disc type, consisting of a pressure plate and cover assembly having 12 release springs, three release levers and a spring-cushioned driven disc mounted on splined hub. There is no internal provision for adjusting the clutch but each release lever is adjusted individually to the correct height. No attempt should be made to adjust these levers unless the clutch is to be dismantled for overhaul. Overhauling the clutch should not be attempted unless a clutch rebuilder is available. Lacking this equipment it is recommended that the clutch cover and pressure plate assembly be exchanged for a rebuilt unit.

Clutch Assembly, Replace

Before removing the clutch from the flywheel, punch mark the flywheel, clutch cover and pressure plate so that these parts may be assembled in their same relative positions and in the same position on the flywheel if the same clutch is to be reinstalled. This is important because they are balanced as an assembly.

After removing the transmission, pull out the clutch release bearing and sleeve. Unfasten the clutch cover from the flywheel, loosening each cap screw a few turns in succession until the cover is free. The clutch and driven disc can then be removed from the flywheel.

When installing the clutch, coat the pilot bearing in the end of the crankshaft with wheel bearing grease. Clean the surfaces of the flywheel and pressure plate, making certain no oil or grease remains on these parts. Hold the cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the pilot bearing in the crankshaft. Bolt the clutch cover loosely to the flywheel, being sure the punch marks previously made are lined up. To avoid distortion of the clutch cover, tighten the cover bolts a few turns in progression until all are tight. Guide the transmission into place, using care to see that the driven disc is not bent. Use a floor jack to support the transmission so that the clutch shaft may be guided through the driven disc safely.

SPICER 2 PLATE UNIT

This clutch, Fig. 7, is a two-plate dry disc type with the two driven plates mounted on the splined clutch shaft. The driving disc, which separates these two plates, is mounted within the flywheel on four pins. As an aid to gear shifting a clutch brake is provided, which comes into action when the clutch pedal is fully released.

Clutch Adjustment

1. Remove the clutch housing cover and check the clearance between the clutch trunnion and the forward side of the clutch brake. If "clearance", Fig. 7, is less than ⅜" or more than ½", adjust as follows:
2. Remove the cap screw and lock on the flywheel ring. Block the clutch pedal in the depressed position and, using a hammer and drift, turn the clutch ring in a clockwise direction to decrease distance between trunnion and brake. Turning adjusting ring counter-clockwise increases clearance.
3. Engage the clutch and recheck clearance, which should be approximately $\frac{7}{16}$".
4. Adjust clutch pedal linkage so that clutch pedal has 1¼ to 1½" free travel at the pedal pad.
5. Idle the engine and check to determine whether or not full release of clutch is obtained before the clutch brake comes into action. Gears should shift freely with no noticeable drag of clutch plates when clutch is held in this position.
6. If clutch does not release before clutch brake comes into action, it will be necessary to readjust clutch as outlined in Step 2.

Fig. 7 Spicer two-plate clutch

7. As a final check, when clutch pedal is fully depressed, it should have a minimum clearance of ½" above the toeboard. Readjust pedal linkage if necessary.

Driven Discs, Replace

1. After removing the transmission, insert two ¾" wooden blocks between the clutch release bearing and the clutch cover plate.
2. Remove cap screw and lock and release the adjusting ring by turning it counter-clockwise.
3. Remove screws attaching spring plate and hub assembly to flywheel.
4. Remove clutch cover plate, pressure plate, driving disc and driven discs from flywheel.
5. Renew clutch plates that are heat checked, cracked, warped or scored. If the clutch lining is scored, oil soaked or worn down to the rivets, it should be replaced or new driven disc assemblies installed.
6. Check clutch pilot bearing and replace if worn. This bearing should be packed with ball bearing grease.
7. Using a spare splined clutch shaft, assemble clutch driven plate, driven discs and cover plate. Driven discs must be assembled with offset hubs as shown in Fig. 7.
8. Bolt clutch to flywheel with dummy shaft in position and the two wooden blocks between release bearing and clutch cover plate.
9. After removal of temporary blocks and dummy shaft, install transmission.
10. Adjust clutch and pedal linkage.

Steering Gear Section

Fig. 1 Ross cam and single lever steering gear with roller stud mounting

Fig. 2 Ross cam and twin lever steering gear with roller stud mounting

ROSS CAM & LEVER

These steering gears, Figs. 1 and 2, are of the cam and lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower stud or studs are pulled along the cam groove causing the lever arm to rotate the lever shaft. As an aid to easy steering the lever shaft stud or studs which engage the cam are mounted on tapered roller bearings. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and cam where most of the steering action occurs.

Cam End Play, Adjust

Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces. Then adjust as follows:

Twin Stud Gears—Loosen the lock nut and adjusting screw in the side cover to free the studs in the cam groove. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of adjusting shims, which are .002", .003" and .010" thickness. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim. If necessary, remove or replace shims until the adjustment is correct.

Single Stud Gears—Loosen the housing side cover adjusting screw to free the stud in the cam groove. Turn down the cam adjusting plug, located at the top of the gear housing, until there is a barely perceptible drag so that the steering wheel can be turned freely with the thumb and forefinger lightly gripping the rim.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then starting from this point count the number of turns required to reach the end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but a slight drag should be felt in the mid-position only.
3. After proper adjustment is secured, tighten the lock nut and give the gear a final check for binding.

Stud Roller Bearing, Adjust

In most cases the foregoing adjustments will be adequate but it is some-

times necessary to adjust the stud roller bearing units as they should be preloaded at all times. A heavy drag should be felt when revolving the studs by hand. If a torque wrench is available the bearings should be adjusted so that the torque required to revolve the stud is as follows:

Lever Shaft Dia.	Torque, In. Lb.
1⅜"	3 to 4
1½"	3 to 4
1⅝"	4 to 8
1¾"	5 to 11

1. To adjust, remove lever shaft from housing, wash the bearings in solvent and blow dry with compressed air, using care not to spin the bearings. Lubricate the bearings with light oil.
2. Straighten out the prong of the locking washer to release the stud nut. Remove the nut and install a new locking washer.
3. While holding the stud nut from turning with a spanner wrench on the locking washer, tighten the nut as required to revolve the stud in accordance with the table above.
4. When proper adjustment has been secured, bend the prong of the washer against a side of the nut to keep it from turning.
5. Lubricate the bearings with gear oil and assemble the lever shaft in the steering gear housing.

ENGINE IDENTIFICATION Divco Engine applications may be identified as follows:

Hercules QXD-3, QXLD-3 and G-298-H is stamped on engine name plate.
Continental F4162 is a flat head four with distributor through cylinder head.
Continental G-4193 is an overhead valve four.
Continental FO-6226 is an overhead valve six with distributor on left side.
Nash 6-252 is an overhead valve six with generator-driven water pump.

Engine Section

CYLINDER HEAD

Overhead Valve Engines

1. Remove all items which would interfere with the removal of the cylinder head.
2. Drain cooling system.
3. Remove intake and exhaust manifolds.
4. Remove rocker arm cover, and push rod cover (if equipped).
5. Remove rocker arm shaft assembly.
6. Remove rocker arm cups or valve caps and identify for reassembly.
7. Grip push rods and snap them sideways out of lifters. Identify push rods for replacement in original locations.
8. Unfasten and remove head.
9. Reverse removal procedure to install the head and tighten down in the sequence shown in Figs. 1, 2 and 3. On G-298H engine, tighten head by starting at the center and work progressively to the outer ends.

Side Valve Engines

In replacing the head, the stud nuts or bolts at the center of the head should be tightened first and then work progressively outward from side to side and to the ends, Fig. 4. Draw the nuts or bolts down evenly until all are normally tight. After the engine has been run long enough to reach normal operating temperature, make a final tightening to the torque specifications listed in the chart.

ROCKER ARMS

1. Disassemble rocker shaft by removing the retaining pin or plug from one end of the shaft and sliding off the component parts.
2. Inspect shaft for wear. If "shoulder" exists, the shaft must be replaced. Blow out oil holes with air.
3. Examine rocker arms for cracks, condition of valve contact surface and worn bushings. Replace all defective rocker arms or any having over .005" clearance between shaft and arm.
4. Check rocker shaft supports for cracks or other damage.

VALVE ROTATORS

Overhead Valve Engines

These rotators revolve each valve (if equipped) a definite amount each time the valve opens. Before an engine is disassembled for valve grinding or major repair work, the performance of the rotators should be checked as follows:

1. Remove rocker arm covers.
2. Observe valve rotation with engine running at moderate speed. The valves should rotate at uniform and constant speeds.

Fig. 1 Cylinder head tightening sequence. Super 6-252

Fig. 2 Cylinder head tightening sequence. FO-6226 engine

Fig. 3 Cylinder head tightening sequence. G-4193 engine

Fig. 4 Cylinder head tightening sequence. OXD, QXLD

3. Rotators that do not appear to be functioning properly should be replaced.

VALVES, REMOVE

Overhead Valve Engines

1. With cylinder head removed, take off rocker arm assemblies and exhaust manifold.
2. Use a suitable spring compressor to compress the valve springs.
3. Remove valve locks.
4. Release and remove spring compressing tool.
5. Remove springs and spring retainers. If burrs exist in lock grooves, file them off before removing valves.
6. Remove valves and place them in a board or rack with numbered holes so that they can be identified as to the valve port from which they were removed.

L-Head Engines

After taking off the cylinder head, remove the valve chamber covers and use a cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so that they can be identified as to the valve port from which they were removed.

VALVE SPRING TESTING

Wash all springs with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 5, and according to the specifications given in the *Valve Data* chart. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 6. If the assembled height is greater than the dimension given in the *Valve Specifications Chart*, install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and

Fig. 5 Checking valve spring tension

overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

VALVE GUIDES

Clean the valve guides with a wire guide brush and check the clearance between valve stems and guides. Excessive clearance will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Valve stem-to-guide clearance may be checked with a dial indicator or a suitable plug gauge. Lacking either of these tools, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check indicates excessive clearance, it will be necessary to replace the valve guide.

If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

Valve guides may be removed and installed with a suitable puller and installer made for the purpose. If such equipment is not available, the old guides can be driven out or they can be pulled out by using a piece of pipe together with a long bolt and suitable washers.

Fig. 7 Valve seat insert puller

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

If refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}$", otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the block for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing the seats has a valve guide pilot.

The valve seat width after refacing should be a liberal $\frac{1}{16}$" for intake seats but not more than $\frac{3}{32}$" in any case. The width of exhaust seats should be $\frac{3}{64}$" to a liberal $\frac{1}{16}$".

Test valves for concentricity with seats and for tight seating. Valves can be tested by lightly coating the valve face with prussian blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.*

After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the tests to see whether a full mark is obtained on the valve. *Both tests are necessary to prove that a proper seat is being obtained.*

VALVE SEAT INSERTS

Since these inserts are too hard to reface by the ordinary hand grinding method, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and that the valve guide pilot is a snug fit in order to assure a concentric finish. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert (if a suitable puller is not available, Fig. 7) drill two holes at opposite sides of the insert but not all the way through. Then cut out the undrilled portion with a sharp chisel and remove the two pieces.

Fig. 6 Checking valve spring installed height

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the new insert with "dry ice" to obtain maximum contraction of the metal and place it in the recess. If necessary, the insert may be pounded in by using a round driver the same size as the insert and pounding on same with a hammer.

If a standard insert is too loose, secure an oversize one. Of course, the recess should be bored out to accommodate the oversize insert.

When installed, peen the block around the insert bore to insure the insert remains in place.

VALVE LIFTERS

F-4162, F-4162S, FO-6226 Engines

Barrel type lifters are used which are the same diameter throughout their length. When necessary, these lifters may be removed from above after taking out the push rods.

G-4193, 6-252, G-298H, QXD, QXLD

These engines utilize mushroom type valve lifters having a base larger than the bore in which they operate. This design makes it necessary to remove the camshaft in order to remove the lifters from below.

On QXD and QXLD engines, if the lifter bores are bushed, the bushings may be pressed out and replaced. After replacement, bushings should be reamed to provide operating clearance.

PUSH RODS

Before installing push rods, inspect them for bends or twists, and examine the ball and cup ends for excessive wear. Any push rod that is defective should be replaced.

Fig. 8 Valve timing. F4162 engine

TIMING GEARS

F-4162, F-4162S, G-4193, G-298H, QXD, QXLD

Camshaft and crankshaft gears should be replaced in pairs, and gears marked similarly with respect to size should be used. Usually, crankshaft and camshaft gears are furnished in standard, undersizes and oversizes. Gears marked "S" are standard; "U" undersize, and "O" oversize. Figures within the latter two letters, such as "1" or "2", would indicate the variation in thousandths of an inch from the standard size. Gears can be selected to give the desired fit.

Crankshaft gear installation may be facilitated by heating it in oil. This will allow it to slide easily on the crankshaft. Light tapping may be required to seat the gear fully.

The camshaft gear may be tapped lightly into place. However, do not allow the camshaft to bump the expansion plug at the rear as this could cause an oil leak. Be certain that the timing marks on the gears are in mesh as shown in Figs. 8 and 9.

Check the gear backlash with gears assembled in place. Pry the teeth as far apart as possible with a screwdriver and check with a feeler gauge. If a .015" feeler gauge will not enter the gap between the teeth, clearance is not excessive.

Fig. 10 Valve timing. FO-6226 engine

TIMING CHAIN

FO-6226 Engine

1. To remove chain and sprockets, remove nut and locking plate on cam sprocket.
2. Pull chain sprockets from camshaft and crankshaft evenly. This can be done with small pry bars, being careful not to damage sprockets or chain.
3. When replacing, be sure to have the chain properly lined up as shown in Fig. 10. Then slide sprockets and chain on crankshaft and camshaft evenly. *Be sure to hold the camshaft forward by installing a pry bar in the fuel pump opening, as failure to do this may loosen the plug at rear of the cylinder block, causing an oil leak.*

CAMSHAFT & BEARINGS

F-4162(S), G-4193, FO-6226, 6-252, G-298H

1. With timing case cover removed, bring No. 1 piston to top dead center.
2. Remove screws retaining camshaft thrust plate to block (not on 6-252). This can be done only with the cam gear removed. If thrust plate indicates scoring or wear, replace without question. (On 6-252 engine, camshaft end thrust is controlled by flanges on the front bearing. If end play becomes excessive, remove the old and install a new front bearing.)
3. In G-4193, 6-252 and G-298H engines, the mushroom type valve lifters must be raised as high in their bores and possible in order to remove the camshaft. The valve lifters can be removed, if necessary, from the bottom of the block after the camshaft and oil pan are removed.
4. On FO-6226 engine, the barrel type lifters are accessible through the push rod chamber cover. On F-4162(S) engines, the lifters may be lifted out through the valve chamber after the valves have been removed.
5. On all engines, remove fuel pump, allowing camshaft to be pulled from block.
6. If necessary to replace camshaft bearings, service bearings are available which require no reaming. Care should be exercised when installing new bearings to properly align the oil holes in the bearings with those in the block.
7. Make certain No. 1 piston is at top dead center when reinstalling camshaft.

QXD, QXLD Engines

The camshaft is supported on four babbitt-lined bearings. Replacement camshaft bearings are cut to allow for a press fit when the bearings are pressed into the block. Therefore, no reaming should be necessary. However, the shaft should be checked in the bearings for proper clearance of .0015-.0025". If there is binding of the camshaft when it is installed, the bearings should be line-reamed to round out the bearing holes, as bearing distortion is likely the cause of the binding condition.

Fig. 9 Valve timing for G-4193 engine. A similar arrangment is used on G-298H and QXLD engines

Camshaft end thrust is controlled by a special screw through the gear cover, Fig. 11. At long intervals or when the engine is disassembled for repairs the end play should be checked. If an adjustment is required, loosen the lock nut and tighten the screw until the fibre plug at its inner end contacts the steel plug in the front end of the camshaft. Then back off the screw 1/8 turn before tightening the lock nut.

The camshaft must be removed in order to install a new camshaft gear. This is done by removing the gear cover, crankshaft oil slinger, and oil pan. Remove the valves and raise the lifters so they will not interfere with the camshaft as it is being withdrawn. The camshaft gear can only be pressed on the camshaft from the rear against the flange on the front end of the shaft.

PISTONS & RODS, REMOVE

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are

Fig. 11 Arrows indicate adjusting screws controlling end play of camshaft, idler shaft and accessory shaft. QXD and QXLD engines

worn so that a ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging ring lands of pistons during removal.

Before removing pistons, mark them with a file (if not already marked) on the inside of the skirt to indicate the bore from which each piston was removed and also its position in the bore with relation to the camshaft side of the engine. Connecting rods should also be suitably marked if they are not marked already.

Remove the connecting rod caps and push the assemblies out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. It is advisable to install caps on rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

If the pistons and rods have factory markings to indicate their position in the cylinders, assemble and install them according to these marks, or according to the marks made during removal if they were not otherwise marked.

PISTONS

Before a honing or boring operation is started, measure all new pistons with a micrometer at points 90° away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is important that refinished cylinder bores are trued up to have not more than .0005″ out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at room temperature (70°) when the piston is checked for fit in the bore. Therefore, the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10° between the temperature of parts is sufficient to produce a variation of .0005″.

PISTON RINGS

When new rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the diameter of the bore. This is done with a "Glazebuster" or a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is to be fitted. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

PISTON PINS

To fit a pin in an aluminum piston, heat the piston in a pail of boiling water for several minutes. Then remove the piston and quickly insert the pin. A good fit is one which requires a light push of the thumb to insert the pin.

For cast iron pistons, a good fit is one which requires a light push with the palm of the hand to insert the pin with both parts at normal room temperature.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the piston and rod assemblies merely by taking off the rod cap and replacing the upper and lower bearing halves.

The clearance between the bearings and crankshaft can be measured with Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the bearing, Fig. 12.
3. Reinstall the bearing cap and tighten the bolts to the torque value given in the *Engine Tightening* table.
4. Remove the bearing cap again and check the bearing clearance by measuring the width of the flattened Plastigage. The measuring strip is supplied in the same envelope which contains the Plastigage.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent

Fig. 12 Checking bearing clearance with Plastigage

bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole, to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten ball cap nuts to the torque value given in the *Engine Tightening* table.

CRANKSHAFT OIL SEAL

G-4193 Engine

The rear crankshaft oil seal is of the "spring" type which keeps the dust out and the oil in. This seal contacts the polished surface of the crankshaft flange, and is pressed into a seal retainer which bolts to the rear of the cylinder block. To replace worn seals, proceed as follows:

1. Remove capscrews attaching seal retainer to block.
2. Remove old seal with a seal driver which fits the seal.
3. Press in a new oil seal.
4. Examine the seal contact surface in the block carefully. Any scratches or other damage to this surface must be polished out before reassembly of the seal to prevent further damage and thus render it ineffective.
5. Mount oil seal and retainer to cylinder block.

F-4162(S), FO-6226

This engine uses the jute-packing type of rear seal. To replace this packing and reassemble the rear seal, proceed as follows:

1. Remove filler block and oil guard, the latter being the semi-circular die casting which fits in the cylinder block in a groove machined just to the rear of the main bearing.

2. Clean all surfaces and grooves thoroughly. If a scraper or wire brush is used, be careful not to scratch or gouge the sealing surfaces. All dried cement or other foreign material must be removed from these surfaces. Check filler block contact faces for flatness; if warped, replace block.
3. The jute packing, as received, has a diameter about ⅓ greater than the width of the grooves. This must be crushed in a vise, or otherwise flattened, narrow enough to be inserted in the grooves.
4. Press flattened packing in both filler block and oil guard as well as possible by hand. Then, using a piston pin, smooth hammer handle or other tool with a smooth rounded surface, iron this packing into the groove so that it is seated firmly and expanded to grip the sides.
5. With a sharp knife or razor blade, cut off the excess packing protruding from the ends of the groove parallel to the surface of the casting, allowing it to protrude 1/32".
6. To assemble to the engine, coat the outer or sealing surface of the oil guard with a non-hardening cement. Slide it into place around the crankshaft if engine is still assembled, or directly into the recess if the crankshaft is out. When the assembly is made as outlined, and the filler block assembled and tightened in place, and completed with a new oil pan gasket, there is no possibility of oil leakage developing at this point.

G-298H Engine

The rear oil seal is mounted in the bellhousing behind the flywheel. The seal is of the one-piece circular spring type and seals against the polished surface of the crankshaft flange. If necessary to replace the seal, the flywheel will have to be removed.

QXD & QXLD Engines

If a new flywheel housing is to be installed or if the engine is disassembled for repairs the clearance between the crankshaft oil slinger flange and the flywheel housing must be carefully controlled to prevent oil leaks.

To measure the clearance, force the crankshaft back to the limit of its end play and insert a feeler gauge between the flange and flywheel housing chamfer. The clearance should be .012-.025", Fig. 13. If necessary to increase the clearance, scrape the chamfer or install an additional gasket between the flywheel housing and the case. To prevent oil leaks, all possible chance of interference or rubbing should be eliminated at this point.

It is important that the oil seal, Fig. 13, be installed concentric with the crankshaft. To prevent rapid wear of this seal, the external pilot of the flywheel hub should be polished with a very fine emery or crocus cloth to remove all nicks and rough spots.

Super 6-252 Engine

Oil sealing at the rear main bearing consists of a steel-backed synthetic rubber seal, Fig. 14. The rubber seal

Fig. 13 Oil sealing at rear of QXD engine

is in halves and fits closely over the edge of the rear main bearing oil return groove. It bears firmly on the smooth area of the crankshaft. Synthetic rubber key strips are used at the sides of the rear main bearing cap. These strips overlap the bearing cap and seal the sides as well as the mating surfaces.

Fig. 14 Oil sealing at rear main bearing. Super 6-252

OIL PUMP

G-4193 Engine

This oil pump is assembled to the front main bearing cap, being held in place by the main bearing capscrews. The drive gear meshes with and is driven by the crankshaft gear (see Fig. 9). These gears have a specified .004-.008" drive or clearance fit which must be checked when reassembling the engine. Shims are available to increase the center distances of the oil pump and crankshaft gears to maintain this fit.

The pressure relief is located on the bottom of the pump body just below the drive gear. Pressure is controlled by a plunger and spring, and may be increased by assembling washers ahead of the cotter pin in the plunger bore.

FO-6226 Engine

This oil pump is externally mounted and driven off a gear on the camshaft. A gear assembled to the upper end of the oil pump shaft is driven by a mating gear cut on the camshaft. A by-pass type of relief is built into the pump so that surplus oil is recirculated.

The oil pressure relief is located externally on the right side of the pump. Pressure is controlled by a plunger and spring, the latter being specifically for a certain range. The only adjustment variation is either to change springs, or assemble or remove washers from behind the present spring. Up to four washers are permissible.

Installation—When installing the oil pump on this engine, the distributor should be removed. If the engine is completely disassembled, the oil pump should be installed only after the crankshaft, flywheel, camshaft and timing gears.

1. Turn engine over to No. 1 firing position. Be certain timing mark on flywheel coincides with pointer on flywheel housing.
2. Position oil pump distributor drive slot as shown in Fig. 15. Note that the slot is offset and that the narrow segment of the shaft is to the top.
3. Place gasket on pump body face, using a small amount of grease to retain it.
4. Insert pump shaft into bore, using care to avoid turning gear before it meshes with drive gear on camshaft. As this occurs, the slot in the shaft will appear nearly horizontal when viewed down the distributor shaft bore.
5. Assemble retaining screws.
6. Chalk-mark the No. 1 terminal position on the distributor body and install the distributor. The rotor should point to this mark when it is installed.

G-298H Engine

Removal

1. Remove oil pan.
2. Turn engine over to place No. 1 piston in firing position.
3. Unfasten and remove pump.

Installation

1. If engine has not been disturbed (No. 1 piston in firing position), install pump and secure in place.
2. If engine has been moved from the

Fig. 15 Installing oil pump on FO-6226 engine

No. 1 firing position, place the piston in firing position. Then turn oil pump drive gear so that flat on flange is to the outside of the pump (side opposite pressure regulator).

3. With flat towards camshaft, insert pump into cylinder block and rotate pump to correct position for attaching screws. *Pump should not be rotated until after drive gear is meshed with gear on camshaft.*
4. Install attaching screws. If distributor was not removed, use care when the pump is installed that the tongue of the distributor drive coupling engages the groove in the pump drive gear with the distributor rotor in firing position for No. 1 cylinder.

Super 6-252

On these engines, the oil pump drive gear which meshes with the camshaft gear is splined to the top end of the oil pump shaft, Fig. 16. The spline is a free fit so that it may be removed from below after the oil pump is dropped. The oil pump drive gear is installed from above after the distributor bracket and gear have been removed.

Fig. 16 Oil pump mountings. Super 6-252

WATER PUMP

G-4193, FO-6226

Disassemble, G-4193

1. Remove bolt from impeller hub and with a puller remove impeller from shaft. *Do not drive or pound on pump shaft or carbon seal on shaft will be damaged.*
2. Remove impeller snap ring and remove seal from impeller hub.
3. If shaft is to be removed, loosen set screw and, with a puller, pull fan hub from shaft.
4. Remove snap ring and press shaft and bearing assembly out of pump body toward the front end.

Disassemble, FO-6226

1. Pull fan hub from shaft, Fig. 17.
2. Remove pump from engine.
3. Remove pump cover by taking out countersunk screws.
4. Use puller to remove impeller. *Do not attempt to drive pump shaft out through rear of housing as housing will be ruined.*
5. Remove seal and water shedder.
6. Remove lock ring holding shaft and bearing assembly in body. Then force shaft out of body with a lead hammer or arbor press.

Reassemble, G-4193, FO-6226

1. Reassemble pump, replacing worn or damaged parts and reverse disassembly procedure. Seal contact surface must be smooth and flat. Bushing should be replaced if scored or cut, but may be refaced and polished for further use if not excessively worn or grooved.
2. Use thick soapsuds on both seal and shaft when assembling to prevent damage to seal.
3. Mount pump on engine using a new housing gasket.

QXLD, G-298H, F-4162(S)

Water pumps used on these engines are fundamentally the same as shown in Fig. 17.

Super 6-252 Engine

A "packless" sealed type water pump is used on these engines. The seal is of "cartridge" construction, installed and serviced as a unit. The sealing member is enclosed in a metal cartridge which is mounted and sealed in the pump body by means of a flexible rubber ring. The sealing member is pressed against the shaft by constant spring pressure exerted through the bushings. The spring chamber also acts as a reservoir for lubricant.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can effect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

ZENITH CARBURETORS

Before making any adjustments on the carburetor, it is important that the breaker points and spark plugs are in good condition and properly set. The ignition timing should be checked and the valves operating properly.

Check all carburetor body and flange screws for tightness and make sure there are no gasket leaks. A typical Zenith downdraft carburetor is shown in Fig. 19.

Fig. 17 Water pump. FO-6226

Fig. 19 Zenith downdraft carburetor

Fig. 20 Float setting. Zenith carburetors

Fig. 21 Carburetor governor adjustment

Float Level

As shown in Fig. 20, measure the distance between bottom of float and machined surface of casting. Hold casting, without gasket, upside down as shown. With float closed, distance indicated should be as given below. To change float setting, bend float lever (close to float body) as required.

Truck models 11, 12, 13.....1 5/32″
Trucks with engine models:
G-4192, FO-6626, G-298H.....1½″
QXLD, F-4162 (S).....1 39/64″

Idle Speed & Mixture Adjustment

The idle adjustment should be set to the highest and steadiest vacuum reading with a vacuum gauge. Idle speed is regulated by the throttle stop screw, Fig. 25. Idle mixture is controlled by the idle adjustment needle. Turning the needle clockwise increases the suction on the idle jet and causes a richer mixture. Turning the needle counter-clockwise causes a leaner mixture.

Accelerating Pump

If the engine does not accelerate properly, remove the air horn assembly and operate the pump with the carburetor bowl full of fuel. Force the pump piston down in its cylinder and note if the air vent check valve leaks. Repeat this operation, noting if the check valve leaks, allowing fuel to be forced back into the fuel bowl through the channel leading from the bottom of the pump cylinder back into the bowl. Repeat this operation again and observe the discharge of fuel at the accelerating jet. If the system is in good condition, a fine, solid, round stream will flow from the discharged nozzle.

Intermediate Operation

If trouble is encountered during intermediate speeds, check all gaskets for tightness. Remove and clean main jet, passages and main discharge nozzle with compressed air.

High Speed Operation

For high speed complaints, check the power valve and high speed restrictions as well as the main jet. Check the fuel pump pressure to see if it is sufficient to maintain proper fuel level in bowl. Float travel should also be observed for full opening of the float needle valve. The vacuum piston should fit properly in place and operate satisfactorily with no air leaks between piston and intake manifold.

CARBURETOR GOVERNOR

If smooth accurate governor action is to be obtained, friction of the throttle shaft and its bearings must be avoided. Most governor failures are due to the accumulation of carbon on the throttle shaft bearings.

Many governor failures can be temporarily corrected without complete disassembly of the carburetor and governor by the application of a good penetrating oil to the throttle shaft bearings. These can be reached by removing the carburetor and applying penetrating oil to the throttle shaft openings on the inside of the throttle body bore. Use care when applying the oil as excessive use will increase carbon formation.

Speed Adjustment

1. Warm up engine to normal operating temperature.
2. Remove seal wire and large seal plug, Fig. 21.
3. To increase speed, turn main spring adjusting screw clockwise; to reduce speed, turn counter-clockwise. *If governor does not show definite response to changes of ¼ to 1 full turn, It indicates a defective governor.*
4. After adjustment has been made, install seal plug and wire.

Surge Elimination

Surge is a condition of intermittent increase and decrease of engine speed. If a surge has developed or the governor is too sensitive, adjust as follows:

1. Romove seal wire and small plug, Fig. 21.
2. Turn compensating spring block adjusting screw ¼ turn counter-clockwise until surge is overcome.
3. Install seal plug and wire.

Slow Governor Correction

If the governor does not respond quickly enough when the governed speed is approached and the action can be considered "lagging" or "flat", adjust as follows:

1. Remove seal wire and small seal plug, Fig. 21.
2. Turn compensating spring block adjusting screw clockwise until "lag" or "flatness" is overcome. *Do not change adjustment more than ½ turn at a time without checking performance of vehicle on the road.*
3. After adjustment has been made, install seal plug and wire.

Clutch, Transmission & Rear Axle Section

For Warner and Divcomatic Transmissions used on Divco trucks, see the "name" chapter for service procedures and lubricant capacities

For Eaton and Timken (Rockwell) driving axles used on Divco trucks, see the "name" chapters for service procedures and lubricant capacities

LONG SEMI-CENTRIFUGAL CLUTCH

This type clutch, Figs. 1 and 2, employs centrifugal force to increase the pressure against the pressure plate and clutch plate at higher speeds, in addition to using conventional spring pressure. The release levers are provided with small centrifugal weights, Fig. 2, which are integral parts of the levers. As the clutch rotates at high speeds, these heavy ends of the levers tend to move outward and exert additional pressure against the pressure plate.

Fig. 1 Layout of Long Semi-Centrifugal clutch parts

Fig. 2 Long Semi-Centrifugal clutch

Clutch Control, Adjust

Unless the clutch control linkage is removed, the only adjustment is the length of the clutch release rod or rods. Before any adjustments are made, first make certain that the pedal shaft and throwout shaft operate freely. The pedal shaft is equipped with bushings and lubricated through grease fittings in the bearing housings. The throwout shaft operates in the clutch housing with grease fittings in the clutch housing.

This rod adjustment is made to obtain proper clearance and thus compensate for normal lining wear. With the foot pedal in its normal raised position, the length of the rod or rods is adjusted to obtain a minimum of $\frac{1}{16}$" free movement between the working face of the clutch throwout bearing and the clutch release levers. This will represent a free movement of the clutch pedal of about $\frac{13}{16}$" on Stand Drive Controls and about 1½" on Sit Drive Controls. Lengthen or shorten the rod or rods to maintain free play at the pedal to insure $\frac{1}{16}$" clearance at the throwout bearing.

On Combination Stand-and-Sit Drive models, with the clutch foot pedal and the clutch and brake pedal in their normal raised position, the length of the slip type release rods are adjusted to obtain a minimum of $\frac{1}{16}$" free movement between the clutch release bearing and release levers. This will represent a free movement of ⅛" at the clutch release rod and the eye pin, resulting in free movement at the pedals of about $\frac{13}{16}$" on Stand Drive Controls and about 1½" on the Sit Drive clutch pedal.

Clutch & Brake Pedal Travel

On Stand Drive models with $\frac{13}{16}$" foot pedal clearance at pedal pad as outlined above, depressing the foot clutch brake pedal about $3\frac{9}{16}$" will completely release the clutch. Further pedal travel will cause no more movement of the throwout shaft due to the design and function of the clutch release cam and rocker arm and roller assembly, but will cause the brake to be applied.

Clutch, Replace

Note—When the clutch is to be removed, the transmission need not be removed completely.

1. Remove clutch and brake pedal pads.
2. Remove front floor, toe boards, front cross panel center, seat bracket and toe and floor board support channel. *While removing channel, disconnect carburetor rod at accelerator cross shaft lever and the cotter pin at the right hand end of the shaft, leaving the accelerator shaft attached to channel.*
3. Remove attaching screw at rear of right hand floor support channel.
4. Disconnect propeller shaft at rear axle, fastening the end in such a way that the shafts do not separate

at the spline.
5. Disconnect clutch release rod or rods at the clutch throwout shaft lever.
6. Disconnect shifter and selector rods at transmission control tower.
7. Disconnect ratchet release rod, speedometer cable and parking brake cable at transmission.
8. Place a bar across from front of rear floor to flywheel bell housing (with block of wood under bar at bell housing). Hang a rope sling from the bar and under the transmission to secure the transmission.
9. Remove clutch housing-to-bell housing attaching screws and slide the transmission back.

When removing the clutch assembly, care should be taken to back out the six attaching screws about three turns at a time successively. This will prevent the clutch cover from being distorted by permitting the tension of the clutch pressure springs to be held by two or three screws.

Do not permit the weight of the transmission to hang on the driven disc for if it is bent it will necessitate excessive pedal travel to release the clutch.

Upon installing, always use a pilot shaft through the driven disc. When assembling the clutch to the flywheel, turn all attaching screws in finger tight. Then tighten with a wrench each screw not over two turns at a time. Go from one side of the clutch to the other until all attaching screws are tightened securely.

Clutch Service

The three release levers are properly set in a parallel plane and permanently locked at assembly. They will require no further attention during the life of the clutch, and they cannot be serviced. The pressure springs are set on asbestos base insulator washers where they rest on the pressure plate.

TRANSMISSIONS

Trans. Removal

Follow the procedure outlined for removing the clutch. In addition, remove the bolts attaching the front of the front propeller shaft, transmission brake drum and transmission companion flange. Then slide the transmission back and out of the vehicle.

Reverse the removal procedure to install the transmission and clutch.

Steering Gear Section

Fig. 1 Gemmer worm and roller steering gear used on all models

GEMMER WORM & ROLLER STEERING GEAR

This type steering gear, Fig. 1, is used on all models. The steering gear worm is integral with the steering shaft and is supported on each end by opposed tapered roller bearings. The triple tooth roller is attached to the roller shaft by means of a steel shaft. Two needle bearing assemblies are installed between this shaft and the roller.

The roller shaft is mounted in the steering gear housing on two needle bearing assemblies which are pressed into the housing. The housing cover is attached to the gear housing by four cap screws. An adjustment screw, mounted in the cover controls roller shaft end play and worm and roller mesh adjustment.

The steering wheel and roller shaft arm (pitman arm) are splined to the steering shaft and roller shaft respectively. Both the pitman arm and steering wheel have master splines to insure correct installation.

Worm End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the four cover screws about 1/8".
3. Use a knife to separate the top shim, passing the blade all the way around between the shims, being careful not to damage the remaining shims.
4. Remove one shim at a time between inspections to remove the end play.
5. The adjustment is correct when there is no end play and no stiffness in the steering gear throughout the complete range of its travel.

Roller Shaft End Play, Adjust

1. Turn the steering gear to either extreme and back 1/8 of a turn.
2. Gripping the pitman arm at the hub, the roller shaft should rotate freely without a particle of end play.
3. If end play exists, adjust as required by means of the roller shaft adjusting screw in the side cover.
4. Be sure to tighten the lock nut securely and inspect for end play and free rotation throughout the entire range of steering gear travel.

Worm & Roller Mesh, Adjust

1. Loosen the roller shaft adjusting screw lock nut.
2. With steering gear in its central position (drag link disconnected) tighten the roller shaft adjusting screw just enough to remove play between the roller shaft roller tooth and worm.
3. Check this by the amount of play felt at the pitman arm. It is better to leave a slight amount of play at this point than to tighten too much.
4. If tightened beyond the point where the lash is removed, serious results will occur which will cause poor steering operation.
5. Tighten the adjusting screw lock nut.

MODEL INDEX & ENGINE APPLICATION

ENGINE IDENTIFICATION—Dodge engines can be identified by the engine serial number located on a machined pad on the cylinder block. The serial number prefix denotes the series letter, followed by engine model, followed by serial number. For example, a 1959 Model M8-400 with a V8-318 engine would read M8-318-000000. However, for 1960 and later engines (except 8-318), the last digit of the engine model is ommitted. Thus, the engine number prefixes for 1960 and later engines are as follows:

Year	Prefix	Engine	Year	Prefix	Engine	Year	Prefix	Engine	Year	Prefix	Engine
1960	TP-23	6-230	1961	TR-17	6-170		TR-36	8-361		TS-25	6-251
	TP-25	6-251		TR-22	6-225		TR-41	8-413		TS-26	6-265
	TP-26	6-265		TR-23	6-230	1962-63	TS-17	6-170		TS-318	8-318
	TP-36	8-361		TR-25	6-251		TS-22	6-225		TS-36	8-361
	TP-41	8-413		TR-26	6-265		TS-23	6-230		TS-41	8-413

⑰—Outer spring.
⑱—Intake 80 @ 1 55/64″, exhaust 57 @ 1 47/64″.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

①—For each 10° rise in temperature subtract .04 volt; for each 10° drop add .04 volt. Temperature is checked with a thermometer 2 inches from installed voltage regulator cover.
②—Current draw at 12 volts while turning rotor shaft by hand.
③—If output is low, stator or rectifier is shorted.

GENERATOR & REGULATOR SPECIFICATIONS

★To polarize generator, reconnect leads to regulator; then momentarily connect a jumper wire from the "Arm" to the "Bat" terminals of the regulator.

①—With power steering 4° to 5°. Caster should be checked with vehicle loaded. If caster cannot be checked when vehicle is loaded the no load caster is approximately 1° to 2° for manual steering and 5° to 6° for power steering. If vehicle wanders caster should be increased. If steering effort is very high, especially when taking corners, caster should be decreased.

②—No load.

③—4000 lb. axle.

④—5000 lb. axle.

⑤—7000 lb. axle.

Engine Section

ENGINE, REPLACE

1952-53 Except C.O.E. Models

1. Take off the hood.
2. Drain cooling system.
3. Remove headlamps.
4. Remove radiator tie rods.
5. Remove radiator hose.
6. Remove radiator shell, radiator core, hood lower side panels and both front fenders as a complete assembly.
7. Remove mat and floorboard.
8. Disconnect propeller shaft.
9. Remove transmission.
10. Remove clutch and brake pedals.
11. Disconnect choke, throttle linkage and vacuum lines.
12. Disconnect exhaust pipe at manifold.
13. Disconnect heat indicator tube and bulb at cylinder head.
14. Disconnect oil gauge line at flexible tube.
15. Disconnect starter cable at starter.
16. Disconnect coil wires.
17. Disconnect windshield wiper hose.
18. Disconnect generator wires.
19. Disconnect starter linkage.

Double rocker arm V8 engine. 1954-59

Single rocker arm V8 engine. 1954-59

20. Disconnect carburetor-to-brake booster line check valve.
21. Remove carburetor air cleaner, horn, breather pipe, ignition coil and brake master cylinder.
22. Remove engine mounting bolts.
23. Lift out engine assembly.
24. Reverse the foregoing procedure to install the engine. The exhaust pipe bracket should be loosened and the engine allowed to run a few seconds before tightening engine mounting bolts and exhaust pipe support brackets. This is important for correct engine alignment.

1952-56 C.O.E. Trucks

1. To remove the engine and transmission without removing the cab, proceed as follows:
2. Drain cooling system.
3. Remove hood.
4. Remove radiator, grille and front fenders as a unit.
5. Remove floor mat and floor boards.
6. Disconnect choke, throttle linkage and vacuum lines.
7. Disconnect generator and horn wires, battery ground cable and coil wires.
8. Remove generator.
9. Disconnect hand brake linkage.
10. Remove body-to-fender tie bar.
11. Remove carburetor air cleaner and driver's seat.
12. Remove crankcase filler pipe.
13. Disconnect universal joint at rear of transmission and install a roller jack under transmission.

Engine lubrication. 1954-59 V8 double rocker arm engines

Engine lubrication. V8-318. By-pass valve shown not used in 1963

14. Disconnect exhaust pipe and carburetor air cleaner pipe.
15. Disconnect clutch and brake pedal.
16. Disconnect oil filter lines.
17. Disconnect oil gauge line at engine.
18. Disconnect brake line to master cylinder.
19. Disconnect thermostat plug from cylinder head.
20. Disconnect speedometer cable at transmission.
21. Disconnect shifting bar.
22. Remove engine support bolts.
23. Install engine lifting fixture.
24. Drain engine oil and remove crankcase.
25. Remove exhaust pipe.
26. Remove crankcase breather pipe.
27. Drop one end of tie rod and swing it out of the way to permit additional travel of the roller jack.
28. Have a helper under the truck push the jack forward gradually while lifting the engine with a chain hoist at the front. When the engine has been moved ahead as far as possible. lower the chain hoist so the engine rests on the front bumper. Keep the jack in place under the transmission and have a helper steady the engine in this position. Then reinstall the engine lifting hook as near the rear of the engine as possible so the engine and transmission will be nearly balanced. Gradually lift the engine with the chain hoist and at the same time have the helper under the truck push the jack forward until the engine and transmission clears the frame cross member and front bumper.
29. To install, reverse the foregoing procedure and bleed the brakes.

1954-56 Six-Cylinder Models (Except C.O.E.)

1. Drain cooling system.
2. Remove battery.
3. Disconnect light wires at both front junction connections.
4. Remove bolts from radiator support.
5. Remove hood center and side panels as a unit.

Engine lubrication. 1954-56 V8-241, 259, 270

Engine lubrication. V8-361, 413

6-170, 225 engine

6. Open both cab doors and note four access holes in each front door pillar. Remove four bolts through access holes (bolts attach fender housing to door pillars).
7. Disconnect upper and lower radiator hoses.
8. Lift fenders, grille panel and radiator from truck as a unit.
9. Remove floor mat and floorboard.
10. Disconnect propeller shaft at front universal joint.
11. Disconnect hand brake.
12. On models with steering column gearshift, disconnect rods at transmission.
13. Remove transmission.
14. Disconnect clutch yoke by removing clevis pin.
15. Disconnect flexible line at fuel pump.
16. Disconnect exhaust pipe at manifold.
17. Disconnect throttle and choke controls.
18. Disconnect heat indicator lead wire.
19. Disconnect oil gauge line at oil line flexible tube.
20. Disconnect starter cable at starter.
21. Disconnect wires from coil.
22. Disconnect windshield wiper hose (if equipped).
23. Disconnect generator wires.
24. Disconnect starter pedal linkage (if equipped).
25. If equipped with brake booster, disconnect carburetor-to-brake booster line check valve.
26. If equipped with air brakes, disconnect air lines at compressor.
27. Disconnect horn wires.
28. Remove carburetor air cleaner, breather pipe and ignition coil.
29. Install an engine lifting bracket on the engine and attach a chain hoist hook to the bracket. Pull chain hoist tight.
30. Remove engine support bolts and lift out the engine.
31. To install, reverse the foregoing procedure.

1954-56 V8-241 & 270 Engines

1. Drain cooling system and oil pan.
2. Disconnect battery, fuel line, electrical connections, and heater duct (if equipped).
3. Remove radiator and front end sheet metal assembly.
4. Remove exhaust pipes.
5. Remove floor cover over transmission.
6. Remove carburetor and attach a suitable engine lifting fixture (Tool C-3162) to carburetor flange studs on intake manifold. Attach chain hoist to fixture eyebolt and pull chain tight.
7. Remove transmission.
8. Remove engine rear support cross member mounting bolts.
9. Remove engine front mounting bolts.
10. Raise engine and at the same time work engine out of chassis toward left front.
11. To install, reverse foregoing procedure.

1955-56 V8-259 Engine

1. Drain cooling system and crankcase.
2. Disconnect battery, fuel line, electrical connections, heater duct (if so equipped), upper and lower radiator hoses, and oil cooler hoses on Powerflite models.
3. Remove radiator and front end sheet metal.
4. Remove exhaust pipes.
5. Attach a chain hoist to engine and pull chain tight.
6. Remove floor mat and floor cover over transmission.
7. On Powerflite models, drain transmission and torque converter.
8. Place jack under rear of engine.
9. Disconnect propeller shaft, speedometer cable, hand brake cable, neutral starter switch wires, back-up light wires and control rods from transmission.
10. Apply hand brake and loosen universal joint companion flange nut.
11. Remove engine front and rear mounting bolts and nuts.
12. Raise rear of engine slightly and remove engine rear support crossmember.
13. On Powerflite models, remove frame center crossmember under transmission.
14. While raising the front and lowering rear end of engine, work engine and transmission forward and up out of chassis.
15. Reverse removal procedure to install engine and transmission.

1954-56 V8-331" Engine

1. Drain cooling system and crankcase.
2. Remove radiator and front end sheet metal assembly.
3. Disconnect clutch linkage and remove transmission.
4. Disconnect negative cable at battery.
5. Disconnect battery cable and lead wires at starter switch, and at generator and distributor.
6. Disconnect fuel lines and remove carburetor air cleaner.
7. Remove carburetor and attach a suitable lifting fixture (C-3060) to carburetor flange studs on intake manifold and attach chain hoist to fixture.
8. Place jack under clutch housing to relieve weight.
9. Remove engine rear support cross member.
10. Remove engine front mounting bolts.
11. Remove jack from under clutch housing.
12. Lift out engine.
13. Reverse the foregoing to install.

1957-59 6-Cyl. & V8 (Except C.O.E. Models)

1. Drain cooling system.
2. Disconnect battery and close fuel tank shut-off valve (if so equipped).
3. Disconnect front light wires and upper and lower radiator hoses.
4. Remove front sheet metal and radiator as a unit.
5. Remove floor boards from driver's compartment.
6. Disconnect propeller shaft at front universal joint.
7. On models equipped with steering column gear shift, disconnect gear shift and selector rods at transmission.
8. Remove transmission.
9. Disconnect clutch yoke by removing cotter key and pin.
10. Disconnect fuel line, wiring and carburetor controls.
11. Remove carburetor, breather pipe and ignition coil.
12. Remove engine from chassis.
13. Reverse removal procedure to install.

1957-59 C.O.E. Models

1. Drain cooling system.
2. Disconnect battery and close fuel shut-off valve (if so equipped).
3. Remove hood center panel.
4. Disconnect front light wires and lower radiator hoses.
5. Remove bumper guards.
6. Lift off grille panel and radiator as a unit.
7. Remove floor boards from driver's compartment.
8. Remove shift lever, hand brake linkage, battery cable, starter wires, speedometer cable and electric shift control.
9. Disconnect propeller shaft at front universal.
10. Remove transmission.

Fig. 1 Cylinder head tightening sequence Double rocker arm V8 engine. 1954-59

Fig. 2 Cylinder head tightening sequence. Single rocker arm V8 engine. 1954-59 and 1960-63 V8-318

11. Disconnect both exhaust pipes at manifolds; also holding brackets.
12. Disconnect oil filter lines (if filter is not mounted on engine).
13. Remove vertical clutch linkage.
14. Remove carburetor and its controls, heat indicator lead wire, oil gauge line, brake air compressor tubes at frame and fire wall (if so equipped), and high and low tension wires.
15. Remove engine supports and lift engine from chassis.
16. Reverse above procedure to install the engine.

1960-63 Six & V8-318

1. Disconnect battery and close fuel tank shut-off valve.
2. Disconnect light wires and radiator hoses.
3. Remove front sheet metal and radiator as a unit.
4. Remove floor boards from driver's compartment.
5. Disconnect propeller shaft at front U-joint.
6. On models with steering column gearshift, disconnect rods at transmission.
7. Remove transmission.
8. Disconnect clutch yoke.
9. Disconnect fuel line at pump, exhaust pipe at manifold, throttle and choke controls, heat indicator lead wire, oil gauge line at oil line flexible tube.
10. Disconnect starter cable at starter, high and low tension wires at ignition coil, generator wires, carburetor-to-brake booster line check valve (if equipped), air lines at compressor if air brakes are used, and horn wires.
11. Remove carburetor, air cleaner, breather pipe and ignition coil.
12. Remove engine support bolts and lift engine from chassis.
13. Reverse foregoing procedure to install the engine.

1960-63 V8-361, 413

1. Remove oil coolant hoses and fuel lines.
2. Remove front bumper.
3. Disconnect tie rods at engine firewall.
4. Remove bolts at radiator yoke.
5. Remove radiator and fenders as a unit.
6. Remove transmission short shaft.
7. Remove transmission.
8. Remove carburetor.
9. Install engine lifting fixture on intake manifold.
10. Remove engine mounting bolts and lift engine out of chassis.
11. Reverse removal procedure to install engine.

CYLINDER HEAD, REPLACE

V8 Engines

Before the cylinder head is removed, first remove the rocker shaft assembly. Slide out the push rods and place them in a numbered rack so that each push rod can be reinstalled in its original position.

When installing a cylinder head, always use new gaskets. Make sure all holes are punched through. Be sure cylinder head enters both dowel guide pins in the cylinder block. Tighten cylinder head bolts in the manner described below.

Extreme care must be exercised when tightening rocker shaft bolts and nuts so that the hydraulic lifters have time to bleed down to their operating length. If the lifters are forced down rapidly, damage to the push rods, lifter bodies or rocker arms will result.

Cylinder head bolts should be tightened down in the sequence shown in Figs. 1, 2 and 3, and to the torque loads listed in the *Engine Tightening* chart.

Side Valve Sixes

After removal, cylinder head should be carefully cleaned and inspected for cracks and plugged water passages. When installing the head, a new gasket should be used and both sides should be coated with a suitable sealing compound. Refer to Figs. 4 and 5 for proper tightening sequence. Tighten to the specified torque after the engine has reached operating temperature. After approximately 20 hours or 500 miles of operation, head bolts should again be tightened to the proper torque while the engine is hot.

Overhead Valve Six

Before installing cylinder head, clean all gasket surfaces of cylinder block and

Fig. 6 Head tightening sequence. Overhead valve six

Fig. 3 Cylinder head tightening sequence. V8-361, 413

Fig. 4 Head tightening sequence for 21-bolt side valve 6-cylinder engines

Fig. 5 Head tightening sequence for 33-bolt side valve 6-cylinder engines

Fig. 7 Top and bottom view of double rocker arm assembly. 1954-59 V8 engine

Fig. 8 Layout of single rocker arm parts. 1954-59 V8 engine

head and install gaskets and spark plugs. Check all surfaces with a straight edge if there is any reason to suspect leakage. Coat new gasket with suitable sealer before installing. Install head bolts and tighten them in the sequence shown in Fig. 6. Repeat the procedure and tighten bolts to the torque listed in the *Engine Tightening* table.

ROCKER ARM SERVICE

1954-59 V8 & 1960-63 V8-318

Sludge and gum formation in the rocker arms and shafts will restrict the normal flow of oil to the rocker arms and valves. Each time the rocker arm and shaft assemblies are removed they should be disassembled and thoroughly cleaned.

When disassembling rocker arms, place all parts on the work bench in their proper sequence to insure correct assembly, Figs. 7 and 8.

Clean all sludge and gum formation from the inside and outside of the shafts. Clean oil holes and passages in the rocker arms and shafts. Inspect the shafts for wear.

1960-63 V8-361, 413

The rocker arms are of stamped steel and are arranged on one rocker arm shaft, per cylinder head. The push rod angularity tends to force the pairs of rocker arms toward each other where oilite spacers carry the side thrust at the rocker arms, Fig. 9.

When installing, the right and left rocker arms must be installed as shown in Fig. 10. The stamped arrow on the rocker shaft must be on top and the arrow must point toward the push rod socket of the rocker arm. This is necessary to provide proper lubrication to the rocker assemblies. The two wide brackets must be installed with the oil feed grooves facing the push rod side of the rocker arm as shown.

Fig. 9 Rocker arms and shaft. V8-361, 413

Overhead Valve Six

To remove rocker arms, take off head cover outlet tube, rocker arm cover and rocker shaft bolts and retainers. Lift off rocker arm and shaft assembly.

Clean all parts. Be sure the inside of the shaft is clean and the oil holes are open. The drilled hole in the bore of the rocker arm must be open to the trough and valve end of the arms. The trough also feeds oil to the adjusting screw and push rod. Assemble and install as follows:

1. Referring to Fig. 11, note flat on forward end of rocker shaft. The flat also denotes the upper side of the shaft. Rocker arms must be put on the shaft with the adjusting screw to the right side of the engine. Place one of the small retainers on the one long bolt and install the bolt in the rear hole in the shaft from the top side.
2. Install one rocker arm and one spacer; then two rocker arms and a spacer. Continue in same sequence until all rocker arms and spacers are on the shaft.
3. Place a bolt and small retainer in front hole in shaft.
4. Place a bolt and the one *wide* retainer through the center hole in the shaft with six rocker arms on each side of center.
5. Install remaining bolts and retainers, separating the four pairs of rocker arms.
6. Locate assembly on cylinder head and position rocker arm adjusting screws in push rods.
7. Tighten bolts finger tight, bringing retainers in contact with shaft *between rocker arms.* Then tighten bolts to 30 ft. lbs.
8. After running engine to normal operating temperature, adjust valve lash to specifications. Complete installation of remaining parts removed.

Fig. 10 Rocker arms installed. V8-361, 413

VALVES, ADJUST

Side Valve Sixes

As a preliminary cold setting, adjust the tappets to .010" on intakes and approximately .003" less than the hot clearance setting for exhaust valves. To obtain an accurate cold setting, adjust each tappet when the cam nose is down. If clearance is set when the tappet is part way up the quieting ramp on the cam, excessive clearance will result when the cam comes down.

When adjusting, be sure the feeler stock is flat and of the correct thickness. The use of old feeler stock that is bent or torn can result in an improper adjustment.

Finish checking the clearance when the engine is at normal operating temperature and running at normal idling speed. Then adjust the tappets to the clearances listed in the *Tune Up & Valve Specifications* table. Page 526

If the truck is to be operated at high speeds for long periods, an additional .002" clearance may be desirable. Be sure the engine is running and hot when allowing for this additional clearance.

Fig. 11 Rocker arms and shaft. Overhead valve six

Fig. 12 Removing valves from V8 engines

Overhead Valve Six

If the cylinder head has been removed, it is good practice to make an initial valve adjustment before starting the engine. Before starting the adjustment, make two chalk marks on the vibration damper. Space the marks about 120 degrees apart (⅓ of circumference) so that with the timing mark the damper is divided into three equal parts. Adjust the valves for No. 1 cylinder. Repeat the procedure for the remaining valves, turning the crankshaft ⅓ turn in the direction of normal rotation while adjusting the valves in the firing order sequence of 153624.

For final adjusment, operate the engine until it attains normal operating temperature. Then adjust valve lash with the engine idling to the clearance listed in the *Tune Up Chart.*

VALVES, REMOVE

Side Valve Engines

After taking off the cylinder head, remove the valve chamber covers and use a cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so that they can be identified as to the valve port from which they were removed.

Overhead Valve Engines

After removing the cylinder head and rocker arm assemblies, use a suitable spring compressor, Fig. 12, to compress the springs. Remove the valve locks and springs, Figs. 13 and 14. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides.

Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

VALVES, GRIND

All Engines

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words the valve head margin must be at least $\frac{3}{64}$", otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face, Fig. 15.

Inspect the valve seats in the block or head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing the seats has a valve guide pilot.

The valve seat width after refacing should be a liberal $\frac{1}{16}$" for intake seats but not more than $\frac{3}{32}$" in any case. The width of exhaust seats should be $\frac{3}{64}$" to a liberal $\frac{1}{16}$".

A simple check can be made to prove the fit of the valve in the valve seat by spreading a thin film of Prussian Blue on the valve face and then inserting the valve in the valve seat. With hand pressure, rotate the valve ¼ turn remove it and observe the transfer of Prussian Blue to the valve face. An uneven transfer of Prussian Blue will indicate an inaccurate valve and valve seat refacing operation.

VALVE SEAT INSERTS

Since these inserts are too hard to reface by ordinary hand grinding methods, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and the valve guide pilot is a snug fit in order to assure a concentric seat. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert, if a suitable puller, Fig. 16, is not available, drill two holes at opposite sides of the insert, but not all the way through. Then cut through the undrilled portion with a sharp chisel to remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the counterbore in the head or block. Then chill the new insert with dry or wet ice to obtain maximum contraction of the metal and drive it in place.

If a standard insert is too loose (less than .002" press fit) a .010" oversize insert is available. Before it can be installed, however, the counterbore in the block or head must be machined to fit the new insert.

VALVE SPRINGS

All Engines

After removing the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring tension fixture, Fig. 17, if one is available. If not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Tune Up &*

Fig. 13 Layout of valves and related parts. Typical of all double rocker arm V8 engines

Fig. 14 Layout of valves and related parts. Single rocker arm V8 engines

Fig. 16 Typical valve seat insert puller

Fig. 17 Fixture and torque wrench for checking valve spring tension

Fig. 18 Valve guide removing tool. Six-cylinder engines

Valve Specifications table within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should be scrapped.

VALVE GUIDES

All Engines

Clean the valve guides with a wire guide brush and check the clearance between valve stems and guides. Excessive clearance between valve stems and guides will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Valve stem-to-guide clearance may be checked with a dial gauge or a suitable plug gauge. Lacking either of these tools, take a new valve and place it in

Fig. 21 Hydraulic valve lifter used on some 281 and larger six-cylinder engines

Fig. 19 Valve guide installing tool. Six-cylinder engines

Fig. 20 Valve guide expansion reamer

Fig. 22 Valve lifter guide installing plate for 281 and larger six-cylinder engines

each guide and feel the clearance by moving the valve stem back and forth. If this check indicates excessive clearance, it will be necessary to correct the condition as outlined below.

If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

1954-59 V8 Double Rocker Arm Engines, V8-361, 413 & Side Valve Sixes

Valve guides in 6-cylinder engines may be removed and installed with the tools shown in Figs. 18 and 19. On V8 engines with double rocker arms, the guides may be removed and installed with special drivers designed for the purpose.

After the new guides have been installed, they should be reamed to round out the holes and to provide adequate operating clearances, Fig. 20.

1954-59 V8 Engines With Single Rocker Arms, V8-318 & Overhead Valve Six

These engines do not have removable valve guides, the valves operating in guide holes bored in the cylinder head. Valves with oversize valve stems are available for service replacement when necessary to ream the guide holes.

Standard production reaming of both intake and exhaust valves is .374-.375". When reaming guides for oversize valve stems do not attempt to ream from standard to .090" oversize. If necessary to ream to that size, use the step procedure of .005", .015" and .030". This must be done in order to maintain a true relationship of the guide to the valve seat. The following chart indicates reamer size and valve stem size.

Reamer Oversize	Valve Stem Size
.005"	.379-.380"
.015"	.389-.390"
.030"	.404-.405"

If an "I" or an "E" is stamped on the cylinder head at the rocker cover gasket boss, all intake and exhaust valves are oversize in that bank, depending upon what letter is stamped.

MECHANICAL VALVE LIFTERS

Side Valve Sixes

In some of the larger engines, valve lifters are carried in removable guide clusters bolted to the cylinder block. When lifters are worn it is usually easier to replace the entire lifter and bracket cluster rather than try to use the old lifters with new brackets and vice versa.

On engines without removable lifter guide brackets, the lifters may be removed, the guides reamed and oversize lifters installed. Oversizes of .001", .008", .030" and .060" are available. To remove lifters from these engines, it is necessary to take out the camshaft, remove the oil pan and take the lifters out through the bottom of the engine.

When reaming lifter guides, the cylinder head and valves will have to be removed so that the reamer pilot can be inserted through the valve stem guide hole.

HYDRAULIC VALVE LIFTERS

Side Valve Sixes

Installed in some of the larger engines (those with removable valve lifter guide brackets) are hydraulic valve lifters of the type shown in Fig. 21. To remove either of the lifter and guide assemblies, proceed as follows:

1. Remove valve cover plates.
2. Turn crankshaft until all lifters in the guide bracket are in the lowest position.
3. Bend locking tabs away from guide bracket attaching bolts and remove bolts.
4. Make certain that the small wire retaining rings are in place on each lifter to prevent lifter from dropping out of guide.
5. Insert a suitable bar into one of the attaching bolt holes of the guide bracket and pry down and out to release the lifters from the valve stems.
6. After lifters are free from the valve stems, work the guide bracket out of the engine.

Service—The plunger is a select fit in the particular cylinder and *must never* be used in any other cylinder since the leak-down rate (metering of oil through lifter) is controlled by the clearance between these parts.

To properly handle hydraulic lifters and guides, construct a rack with holes in it large enough to hold the various parts. Place the parts in the rack as they are removed so that each unit can be reassembled as it was originally installed.

Disassembly—Remove the retaining rings from the lifters and take the lifters from the guides. Taking each lifter in turn, remove the cylinder by drawing it out of the lifter body. Remove the plunger by pulling outward and twisting in a clockwise direction. This will detach the spring from the recess in the cylinder body.

Inspection—Wash all parts and dry with compressed air. Examine the lifter face, body, plunger and cylinder for wear. If any of these parts show evidence of looseness or damage the complete unit should be replaced.

To test the ball check valve, suck on the oil inlet tube and seat the ball. If no leakage exists, the vacuum created will keep the tube attached to the tongue. If vacuum in the tube disappears, the complete lifter must be renewed since the ball check is leaking.

With plunger and cylinder dry and clean, place the plunger into the cylinder and squeeze them together between thumb and forefinger. The plunger should be springy and riding on a cushion of trapped air. If leakage is evident, clearance is too great and the complete lifter should be replaced. Make certain that the check ball valve is seated when making the latter test.

Fig. 23 Hydraulic valve lifter of the flat valve type. V8 engines

Reassembly—Insert the plunger into the cylinder (dry) and turn clockwise, while pushing in until the spring seats in the counterbored recess in the cylinder. At the same time, release the trapped air by inserting a toothpick or wood match into the oil inlet tube to unseat the ball check valve. Insert plunger and cylinder in body. Then install the lifters into the proper location in the guide bracket and install the retaining rings.

Installation—Make certain the camshaft lobes are positioned so that all lifters for a particular assembly will be in the lowest possible position. Make an Installing plate to the dimensions shown in Fig. 22 from smooth sheet metal. Place the assembly in the engine and position the installing plate on top of the lifters and under the valve stems. Push the lifter guide assembly into place and align it with the cylinder block bolt holes. Remove the installing plate, and install the bolts and lock by bending up the corners of the locking plate.

Start the engine and make sure oil is reaching all lifters and that each lifter is functioning properly. A properly working lifter will function without noticeable plunger spring action a few minutes after the oil pressure reaches them.

Install the cover plates, using new gaskets, and make sure there are no oil leaks.

V8 Hydraulic Lifters

Figs. 23 and 24 illustrate the type of

Fig. 24 Hydraulic valve lifter of the ball check type. V8 engines

Fig. 25 Removing stuck hydraulic lifter with special tool. V8 engines

hydraulic valve lifters used. Before disassembling any part of the engine to check for noise, check the oil pressure at the gauge and the oil level in the oil pan. The pressure should be between 40 and 65 pounds at 1500 rpm. The oil level in the pan should *never be above the "full"* mark on the dipstick, *nor below* the "add oil" mark. Either of the two conditions could be responsible for noisy lifters.

Oil Level Too High—If the oil level is too high it is possible that the connecting rods can dip into the oil when the engine is running and create foaming. This foam is fed to the hydraulic lifter by the oil pump, and air gets into the lifters, causing them to go flat and allow the valves to seat noisy.

Oil Level Too Low—Low oil level may allow the oil pump to take in air which, when fed to the lifters, causes them to lose length and allows the valves to seat noisily. Any leaks on the intake side of the oil pump through which air can be drawn, will create the same lifter action. When the lifter noise is due to aeration, it may be intermittent or constant, and it will always cause more than one lifter to be noisy. When the oil level and leaks have been corrected, the engine should be run at a fast idle for sufficient time to allow all of the air inside of the lifter to be worked out.

To determine the presence of lifter noise, remove the rocker arm covers and reinstall the spark plug wires. Run the engine at idle. Feel each rocker arm to determine which is noisy. The noisy lifter can readily be detected by feel. It should be remembered, however, that worn valve guides or cocked springs are sometimes mistaken for noisy lifters. If such is the case, the noise in all probability will be dampened by applying side thrust on the valve spring with a hammer handle. If the noise is not appreciably reduced, it can then be assumed that the noise is in the hydraulic lifter.

Valve lifter noise can be described as a "light noise" or a "heavy noise". A "light noise" is usually caused by excessive leakdown around the unit plunger or a partially sticking plunger in the cylinder.

A "heavy noise" is caused by either the valve not seating or by foreign particles becoming wedged between the plunger and cylinder, causing the plunger to stick in the down position. This "heavy noise", of course, will be further evidenced by clearance between the valve stem and rocker arm as the valve closes. A "light noise" caused by a lifter can be determined by pushing down the push rod end of the rocker arm. The noise will become more audible, and if the push rod end of the rocker arm is held down long enough, the intensity of the noise may increase. In either instance, the unit assembly should be removed for further inspection and cleaning.

Lifter, Replace

In removing a lifter, Chrysler Tool C-3158 is available for the operation. Insert the hooked portion of the tool in the lifter body. (This portion of the tool can be used to remove lifters without a varnish build-up around the bottom of the body). Lift the lifter out of the bore. If they are stuck, proceed as follows:

Slide the puller portion of the tool through the cylinder head push rod holes and seat it firmly in the top of the lifter, Fig. 25. Insert the puller pin through the body and tool shaft in the holes provided. Grasp the tool handle and pull the lifter out of the bore. As the lifter clears the bore, withdraw the puller pin and remove the tool.

When installing hydraulic lifters in the engine, fill them with light engine oil (10W) to avoid excessive time required to quiet them during initial operation of the engine.

Servicing Lifters

Warning—Hydraulic plungers and bodies are not interchangeable. Therefore, it is advisable to work on one lifter at a time to avoid mixing parts. *Mixed parts will not function.* Moreover, do not mix check valves as they may be slightly worn and will fit only the plungers with which they have been operating.

Testing Lifters

In testing a lifter, secure a container deep enough to completely immerse the lifter assembly. Fill the container with clean kerosene. Remove the cap from the plunger and submerge the lifter. Allow the cylinder to fill with kerosene. Then remove the lifter and replace the cap.

Holding the lifter upright, insert the lower jaw of the pliers shown in Fig. 26 in the groove of the lifter body. Engage the upper jaw of the pliers with the top of the plunger cap as shown. Check the leakdown by compressing the pliers. If the plunger collapses almost instantly, disassemble the unit, clean it again and retest. If the lifter still does not function satisfactorily, install a new unit, being sure to test the new one before installing it in the engine.

Fig. 26 Testing hydraulic valve lifter. V8 engines

TIMING CHAIN OR GEAR COVER

218, 230, 237, 251, 265 Side Valve Sixes

When installing the chain case cover on these engines, place a new gasket in the cover, then drive the oil seal in position, using a drift or a flat piece of metal slightly larger than the seal to assure a tight, even contact between the seal and its seat.

When fastening the cover, care must be used to center the seal on the crankshaft before tightening the cover screws. A special centering tool, Fig. 27, is available to make the installation. When using this tool, first tighten the screws only enough to hold the cover in place. Then insert the tool, holding it by the crankshaft starting jaw, tightening the jaw nut only finger tight. As the cover screws are being tightened and the gasket is being compressed, tighten the jaw nut, maintaining a slight tension between the centering tool and the seal. Then remove the tool, install the starting jaw and tighten it to a minimum of 108 lb. ft. torque.

281, 306, 331, 377, 413 Side Valve Sixes

Check the pulley for burrs or other roughness that might damage the seal before installing the pulley on the cover. With a suitable driver, drive a new seal into the gear cover after coating the outer diameter of the seal with white lead or gasket sealer. Install a new cover gasket and the cover on the engine, being careful not to damage the seal. Install the capscrews and tighten them against the lock washers without compressing the lock washers.

Install the crankshaft pulley and pull it into the cover with the starting jaw nut. The pulley will align the seal and cover. Tighten the cover screws and starting jaw nut alternately until the cover screws are tightened to 15 lb. ft. torque. Then tighten the starting jaw nut to 135 lb. ft. minimum.

V8 Engines

Whenever the cover is removed be sure to install a new oil seal. And when installing the cover, guard against water and oil leaks as suggested in Fig. 28.

Fig. 27 Special centering tool for timing chain cover oil seal. For 265 and smaller six-cylinder engines

Fig. 29 Valve timing. All six cylinder engines

Fig. 31 Valve timing on V8 gear-driven engines. View shows fuel pump eccentric being installed

TIMING CHAIN

Chain-Driven Engines

For correct valve timing, the timing chain and sprockets should be assembled as shown in Figs. 29 and 30.

If there is more than ½″ slack in the chain as indicated in Fig. 29, replace the chain.

TIMING GEARS

Gear-Driven Engines

For correct valve timing, the timing marks on the camshaft and crankshaft gears should be matched. Fig. 31 shows the installation on V8 engine.

CAMSHAFT & BEARINGS

Side Valve Sixes

All camshaft bearings (except the rear) are removable. Replacement is usually performed when the engine is removed for overhaul. If the bearing clearance is excessive, finished bearings which require no reaming, scraping or burnishing, are available provided the proper tool, which draws all bearings into place at one time, is used.

The desired camshaft bearing clearance is .002-.004″. To measure bearing wear, attach a dial indicator to the block with the plunger of the indicator resting on the camshaft nearest a bearing. Pry the shaft to and from the indicator so that this movement will be shown on the indicator. Check all bearings in the same manner. If the clearance exceeds .004″, a new camshaft may be installed (for test purposes only) to recheck the bearings. With the new camshaft installed, clearance should not exceed .002″. If it does, replace the bearings.

If bearings replacement is necessary, remove the fan drive pulley or vibration damper and timing chain or gear case cover. Lift the valves (if installed) and tappets and hold them up with clothespins, Fig. 31A, or other suitable means. (On engines with removable tappet guide brackets, remove the brackets and tappets.) Pull out the camshaft.

Camshaft end play is controlled by a thrust plate behind the camshaft gear or sprocket. End play should be held to .006″ and can be measured with a feeler gauge between the camshaft hub and thrust plate. If end play is excessive, press off the thrust plate and install a new one.

V8 Engines

If camshaft bearings are to be replaced the engine should be removed from the chassis and the crankshaft taken out in order that any chips or foreign matter may be removed from the oil passages.

Drive out the camshaft rear welch plug. Special equipment is required to remove and install camshaft bearings. This tool pulls out all the bearings at once and installs the new bearings at one time.

When installing bearings, be sure the oil holes in the bearing line up with the oil holes leading to the main bearings.

Install a new welch plug in the rear of the block. Install the thrust plate on the camshaft and press on the hub and key. The hub is properly installed when a feeler gauge .002-.006″ can be inserted between the hub and thrust plate.

Fig. 31A Camshaft assembly. Overhead valve six

Fig. 28 Installing chain case cover. V8 chain-driven engines

Fig. 30 Valve timing on V8 chain-driven engines

Fig. 32 Method of holding up valves and tappets for camshaft removal on side valve chain-driven sixes

Overhead Valve Sixes

The camshaft is supported by four precision type, steel-backed, babbitt-lined bearings. Rearward thrust is taken by the rear face of the sprocket hub, contacting the front of the engine block.

The camshaft, Fig. 32, can be removed after removing the grille, radiator and timing chain. To remove the camshaft bearings the torque converter or flywheel must also be removed.

1. Remove valve lifters, oil pump and distributor.
2. Slide camshaft out of engine.
3. Remove welch plug back of rear camshaft bearing.
4. Remove bearings with suitable puller equipment.
5. Install new bearings, being sure the oil holes in bearings line up with corresponding oil holes in crankcase.

PISTONS & RODS, REMOVE

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. Make sure rods and pistons are properly numbered so they can be reinstalled in the proper cylinders. It is advisable to install caps on rods to avoid mixing parts.

PISTON & ROD, ASSEMBLE

Side Valve Sixes

When assembling the piston to the rod, the slotted side of the piston should be opposite the oil hole in the rod. Install the assembly in the cylinder so that the oil hole in the rod is toward the valve side of the engine.

Overhead Valve Six

Piston and rod assemblies must be installed with the notch on the piston head toward the front of the engine, and the oil hole in the connecting rod toward the manifold side of the engine.

All V8 Engines

When installing piston and rod assemblies in the cylinders, the compression ring gaps should be diametrically opposite one another and not in line with the oil ring gap. The oil ring expander gap should be toward the outside of the "V" of the engine. The oil ring gap should be turned toward the inside of the engine "V".

Immerse the piston head and rings in clean engine oil and, with a suitable piston ring compressor, insert the piston and rod assembly into the bore. Tap the piston down into the bore, using the handle of a hammer.

Fig. 32A Correct assembly of pistons and rods. V8 engines

Assemble and install the pistons and rods as shown in Fig. 32A.

PISTONS, REPLACE

Before a honing or boring operation is started, measure all new pistons with a micrometer at points exactly 90 degrees away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is very important that refinished cylinder bores are trued up to have not more than .0005" out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at the same temperature (room temperature of 70 degrees) when the pison is checked for fit in the cylinder bore. Therefore, the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10 degrees between the temperature of parts is sufficient to produce a variation of .0005".

With the piston rings and pin removed and cylinder wall and piston clean, insert the piston upside down in the bore. Use a feeler ½" wide which is long enough to extend the full length of the piston. The thickness of the feeler should be the same as the clearance given in the *Pistons, Rings & Bearings* table. With the feeler hooked to a spring scale, a pull of 5 to 10 lbs. should be required to pull the feeler past the piston.

PISTON RINGS, REPLACE

When new rings are to be installed without reboring cylinders, the glazed cylinder wall should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is fitted. An inverted piston can be used to push the rings down to this position. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If the feeler gauge is inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance may result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

PISTON PINS, REPLACE

Overhead Valve Six

Piston pins should be a very light thumb press fit in the piston with the parts at normal room temperature (70°). Piston pins are supplied in standard size only. If excessive clearance is noted, both piston and pin should be replaced.

V8's and Side Valve Sixes

The fit of both the piston and connecting rod should be a tight thumb press fit with the parts at normal room temperature.

When using an expansion reamer to fit piston pins, start off by taking a very light cut. Try the fit. Then ream and try the fit again until the pin can be pushed into the rod and piston as described above.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the piston and rod assemblies merely by taking off the rod cap and replacing the upper and lower bearing halves.

The clearance between the bearings and crankshaft can be measured with Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing.
2. With crankpin at approximately

Fig. 33 Crankshaft rear oil seals. Six-cylinder engines

bottom dead center, place a piece of Plastigage in the center of the bearing.

3. Reinstall the bearing cap and tighten the bolts to the torque value given in the *Engine Tightening* table.
4. Remove the bearing cap again and check the bearing clearance by measuring the width of the flattened Plastigage. The measuring strip is supplied in the same envelope which contains the Plastigage.

MAIN BEARINGS

V8's & Overhead Valve Sixes

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole, to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening* table.

Side Valve Sixes

Main bearings can be replaced after removal of the oil pan. Both standard and undersize bearings are available for service replacement.

Never use a new bearing half with an old bearing half. Never file or shim original bearing caps in an attempt to fit bearings.

To install a new set of bearings, proceed as follows:

1. Remove oil pan, clutch housing pan and oil suction pipe.
2. Disconnect chain case cover from the oil pan seal and remove oil pan gasket seal plate.
3. Loosen bearing caps slightly.
4. Remove one cap at a time and replace both upper and lower bearing shells.
5. Before installing bearings, be sure crankshaft is not nicked or scored.
6. Measure clearance between bearing and crankshaft when installing either old or new bearings.
7. Plastigage may be used to measure clearance. Lacking Plastigage, however, coat a piece of .0015″ brass shim stock (½″ wide and 1″ long) with oil and place it between the bearing and crankshaft.
8. Install the bearing cap and draw it up tight.
9. If the clearance is not excessive, there will be a slight drag when the crankshaft is turned.

CRANKSHAFT OIL SEAL, REPLACE

Side Valve Sixes

Locate the seals and gaskets carefully before the rear main bearing cap is installed, Fig. 33. To replace the upper seal, it is necessary to remove the flywheel.

V8's & Overhead Valve Six

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the lower half of the seal become damaged during servicing, replacement can be made as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position and roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Fig. 34 Oil pump on six-cylinder engines

Fig. 35 Oil pump. Typical of all V8 engines

OIL PUMP REPAIRS

Side Valve Sixes

External Mounting Type—To remove the pump, first remove the distributor cap and rotate the engine until the distributor rotor is in firing position for No. 1 cylinder. Keep the engine in this position while the pump is off. The pump may then be removed from the engine.

To disassemble the pump, Fig. 34, remove the cover and gasket. Hold a hand over the cover opening and with the pump upside down, turn the shaft until the outer rotor slips out. Drive out the pin securing the drive gear to the shaft, press the shaft out of the gear and slide the shaft and inner rotor out of the body.

Before installing the pump, see whether the distributor rotor is in No. 1 firing position. Then after installing the pump, check and set the ignition timing.

Internal Mounted Type—Remove the oil pan to reach the oil pump. Unfasten the pump from the engine and service it in same manner as the externally-mounted pump.

V8 Engines

After removing the pump from the engine it should be disassembled, cleaned and inspected for wear or damage, Fig. 35.

1. Remove the cotter pin holding the oil strainer to the oil suction pipe. Then remove the pipe from the pump body.
2. Remove the pump cover and discard the oil seal ring.
3. Remove pump rotor and shaft and lift out rotor body.
4. Remove oil pressure relief valve plug and lift out the spring and plunger.
5. Wash all parts in cleaning solvent and inspect carefully for damage or wear.

Fig. 35A Oil pump and filter. Overhead valve six

Fig. 36 Bushing type water pump. Light duty six-cylinder engines

6. The mating face of the oil pump cover should be smooth. If it is scratched or grooved, the cover should be replaced with a new one.
7. Check for excessive cover-to-rotor wear by laying a straight edge across the cover surface. If a .0015″ feeler gauge can be inserted between cover and straight edge, the cover should be discarded and a new one installed.
8. Measure the diameter and thickness of the rotor body with a micrometer. If the rotor body measures less than .998″ and the diameter less than 2.244″, install a new rotor body.
9. Measure the thickness of the pump rotor. If it measures less than .998″, a new rotor should be installed.
10. Slide rotor body and rotor into pump body and then place a straight edge across the face of the pump body between the bolt holes. If a feeler gauge of more than .004″ can be inserted between the rotors and straight edge, install a new pump body.
11. Remove the pump rotor and shaft, leaving rotor body in pump cavity. Press rotor body to one side with the fingers and measure the clearance between rotor and pump bodies. If it is more than .012″, install a new pump body.
12. Check the clearance between the pump rotor and rotor body. If the measurement is more than .010″, install a new pump rotor and rotor body.
13. Check the oil pump relief valve plunger for scoring and free operation in its bore. If the plunger is scored, install a new one.
14. When assembling the pump, be sure to use a new oil seal ring between the cover and body. Tighten cover bolts

Fig. 37 Water pump with integral bearing and shaft. Six-cylinder engines

Fig. 38 Water pump with removable bearings. Six-cylinder engines

Fig. 40 Water pump. Overhead valve six

Fig. 39 Water pump with removable bearings. Typical of all V8 engines

Lubrication diagram for Slant Six engines

to a torque of 10 lbs. ft.

15. Prime the pump. Then place a new oil seal ring in the pump mounting face. Install oil pump and strainer and fasten the pump in position, tightening the bolts with a torque wrench to 35 lbs. ft.

Overhead Valve Six

Remove oil pump attaching bolts and remove pump and filter assembly from side of engine. When installing the pump tighten the attaching bolts to 200 inch lbs.

Refer to Fig. 35A and remove the pump cover seal ring. Press off the drive gear, supporting the gear to keep load off aluminum body. Remove rotor and shaft and lift out outer pump rotor. Remove oil pressure relief valve plug and lift out spring and plunger.

Inspection

1. The rotor contact area and the bores of the shaft and valve in the pump body should be smooth, free from scratches, scoring or excessive wear.
2. The pump cover should be smooth, flat and free from scoring or ridges. Lay a straightedge across the cover. If a .0015″ feeler gauge can be inserted under the straightedge, the cover should be replaced.
3. All surfaces of the outer rotor should be smooth and uniform, free from ridges, scratches or uneven wear. Discard a rotor less than .649″ thick and/or less than 2.469″ in diameter.
4. The inner rotor and shaft assembly should be smooth, free from scoring and uneven wear. Discard rotors less than .649″ thick.
5. Place outer rotor in pump body and measure clearance between rotor and body. Discard pump body if clearance is more than .012″.
6. Install inner rotor and shaft in pump body. Shaft should turn freely but without side play. If clearance between rotor teeth is more than .010″, replace both rotors.
7. Measure rotor end clearance. If feeler gauge of more than .004″ can be inserted between straightedge and rotors, install a new pump body.
8. The oil pressure relief valve should be smooth, free from scratches or scoring, and should be a free fit in its bore.
9. Relief valve springs are painted either gray, red or brown to denote free lengths of $2\frac{3}{16}$, $2\frac{19}{64}$ and $2\frac{25}{64}$ inches. Rather than change the length, replace a spring with one of the same color.

WATER PUMP REPAIRS

Figs. 36 to 39 illustrate the various type water pumps used on these engines. When servicing a pump be sure to install the seal parts correctly.

Inspect the face of the pump body against which the sealing washer turns. This surface should be smooth and free of scores. Reface with a suitable tool if necessary. Discard the pump impeller if it is corroded or loose on the shaft.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

Carburetor & Governor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if the fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading on carburetors with automatic choke may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Automatic Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

CARTER NOTES

Fig. (1)—BBD and BBS float level.

(2)—With throttle valves closed and pump connector rod in middle hole in throttle lever the distance between top of bowl cover to top of plunger shaft should be as listed. Adjust by bending pump connector rod at lower angle.

(3)—See (1). Flat top floats 9/32", curved top floats 7/32".

(4)—With throttle valve fully closed and with throttle connector rod in center hole of throttle lever the distance from top of bowl cover to top of plunger shaft should be as listed. Adjust by bending throttle connector rod at lower angle.

CARTER NOTES continued

⑤—Remove choke thermostat, housing and baffle plate. Crack throttle and hold choke valve fully closed. Then close throttle. This will allow fast idle cam to revolve to fast idle position. There should now be the clearance listed between throttle valve and carburetor bore (side opposite idle port). Adjust by bending choke connector rod at lower angle.

⑥—This adjustment must be made after the fast idle setting. Hold throttle valve wide open and close choke valve as far as possible without forcing. There should now be the clearance listed between upper edge of choke valve and inner wall of air horn. Adjust by bending arm on choke trip lever.

⑦—Maximum dashpot action is obtained by loosening lock nut and adjusting dashpot unit so that dashpot plunger shaft can be moved inward the distance listed with throttle valve fully closed.

Fig. ⑧—BB and BBR2 float level. Place .050" gauge between spring loaded pin and float lip when checking float level on units having springloaded needle.

⑨—With air horn removed, back out throttle adjusting screw and be sure pump link is in center of throttle shaft arm. Distance pump should travel from fully closed throttle position to fully open position should be as listed. Adjust by bending horizontal portion of pump lifter link.

⑩—Adjusting screw (in top of bowl cover) should be opened 5 turns listed from the closed position.

STROMBERG NOTES

Fig. (1)—WW float level.

(2)—With throttle valves fully closed, distance from top of pump plunger rod to top of air horn should be as listed. Adjust by bending pump connector rod.

Fig. (3)—With pump connector rod in center hole of throttle lever, back off idle speed screw until throttle valves are fully seated and fast idle adjusting screw is off the fast idle cam. To adjust, bend pump connector rod at the lower angle to obtain the dimension listed.

(4)—Turn idle speed screw out to clear throttle lever tang when throttle valves are closed. Hold throttle valves closed and turn fast idle screw out until it is positioned on high step of fast idle cam. From this position turn fast idle screw in 6½ turns. At this point a $\frac{9}{32}''$ drill should fit between choke valve and air horn wall. Adjust by bending fast idle rod at upper end.

(5)—Hold choke valve lightly closed and open throttle valves wide open. It should now be possible to insert the drill size listed between choke valve and air horn wall. Adjust by bending tang on throttle lever.

(6)—Index mark should be set midway between L and R marks.

(7)—With throttle valves fully closed turn fast idle screw in so it just contacts throttle lever. Then turn screw in 4½ turns on V8's and 5⅛ turns on 6-cyl.

(8)—With idle speed screw set for normal idle speed, there should be the clearance listed between the end of the dashpot plunger and ear on throttle lever when plunger is pushed to end of its travel. To adjust, turn dashpot in its bracket.

(9)—With throttle valves fully closed turn fast idle screw in so it just contacts throttle lever. Then turn screw in 5½ turns.

(10)—With throttle valves closed, turn fast idle adjusting screw out until it rests on high step of fast idle cam. Then turn fast idle screw in three turns. In this position a $\frac{13}{64}''$ drill should fit between edge of choke valve and air horn wall. Adjust by bending fast idle rod.

(11)—Pump travel is automatically correct when bowl vent is properly adjusted. To adjust bowl vent, have throttle valves fully closed, pump rod in medium stroke hole in throttle lever and bowl vent clip in center notch on pump stem. Now a $\frac{5}{64}''$ drill should fit between bowl vent and vent seat. If not, adjust by bending pump rod as required.

(12)—Fast idle cam position adjustment: Turn idle speed adjusting screw out until throttle valves seat in their bores. Position fast idle cam so that fast idle adjusting screw contacts top step of cam with throttle valves seated; it will be necessary to turn out fast idle adjusting screw. To adjust, bend fast idle rod at upper angle until the dimension shown exists between upper edge of choke valve and the bore of the air horn. Engine fast idle speed adjustment: With engine warmed up and running, set engine rpm at 1250 with fast idle adjusting screw resting on top step of cam.

CARTER GOVERNOR

Before making any governor adjustments, the engine must be tuned to the manufacturer's specifications. Run the engine until normal operating temperature is reached.

To adjust the governed speed, remove the large cap screw and gasket, Fig. 1 and with a screwdriver, turn the primary adjusting screw clockwise to decrease engine speed, and counterclockwise to increase engine speed.

Do not turn the screw out beyond the end of the governor housing to the extent that it will interfere with the complete tightening of the screw cap. If the adjusting screw is turned too far out the primary spring can become disengaged from the adjusting screw.

Fig. 1 Carter velocity governor

KING-SEELEY GOVERNOR

This governor, Fig. 2, is mounted between the carburetor and intake manifold and automatically governs the maximum speed at which the engine may be operated.

The gas mixture rushing from the carburetor through the governor throat strikes the offset throttle valve and tends to draw it closed. This action is opposed by a governor spring which is attached to the valve shaft through a cam ribbon and cam. By adjusting the pull of this spring, the governor valve may be made to remain open, and then closed at a predetermined engine speed. Adjustment of the spring pull is accomplished by changing the number of coils operating.

Fig. 2 King-Seeley velocity governor

Governor Adjustment

All governors are calibrated and adjusted in assembly to insure accurate control of the maximum engine speed of the model vehicle for which it is intended. However, there will be occasions when minor adjustments are required to satisfy local conditions where the truck is operating.

To adjust a governor for higher speed, turn the adjusting cap counter-clockwise or to the left; for lower speeds turn the cap to the right or clockwise. One turn on the adjusting screw will change the speed 300-400 rpm or between 4 and 5 mph.

When a more sensitive regulation is desired or if the governor is too sensitive and inclined to surge, correct the adjustment as follows by means of the calibrating nut shown at "A", Fig. 3.

If Governor is too Sensitive—If the governor is too sensitive or on the point of surging, remove the adjusting cap and hexagonal shaft assembly and place the special hollow wrench (A-24283) in position on nut "A". Insert the special adjusting wrench (A-25264) through this wrench and turn the main adjusting screw "B" to the right one turn. (These wrenches are available at King-Seeley Distributors.) With the hollow wrench in the slot of nut "A", turn this nut to the right about ¼ turn. The main adjusting screw "B" must be kept from turning while nut "A" is adjusted.

If Governor is Not Stable—If a more sensitive governor is desired, adjust main screw "B" to the left one turn and, while holding this screw in the new position, turn nut "A" to the left ¼ turn at a time until the desired regulation is obtained. When the adjustment is completed, tap lightly on the end of the hollow wrench so that nut "A" will seat properly.

MECHANICAL GOVERNOR

1960-63

The mechanical governor is mounted on the distributor support housing and is gear driven from the distributor. It is lubricated by engine oil through the restrictor elbow in the governor housing. The tachometer cable is driven by nylon gears at the upper end of the governor shaft. The tachometer gears are sealed away from engine oil and should be cleaned and lubricated with lubricant at intervals.

Fig. 3 King-Seeley governor adjustments

Adjustment

Before adjusting the governor for specified engine speed, the linkage to the carburetor should be adjusted to a length which will permit full carburetor throttle opening when the governor lever is full forward.

1. Remove governor adjusting (lower) nut from spring anchor bolt.
2. Remove linkage from governor lever.
3. Pull *lower* section of governor lever forward while guiding spring anchor bolt upward to relieve spring pressure. Hold governor lever forward against its (internal) stop.
4. Pull linkage forward to full throttle position.
5. Linkage should enter outer section of governor lever when lever is against its stop on lower lever. Adjust linkage length, if necessary, and connect to governor.
6. Install nut on spring anchor bolt to approximate original position.
7. Start and run engine until it reaches operating temperature.
8. Adjust tension on governor spring for desired engine rpm. Increasing the tension increases engine speed and vice versa. Tighten jam nut.

Clutch Section

CLUTCH PEDAL, ADJUST

D100, D200 Six-Cyl.

1. Adjust clutch release overcenter spring adjusting end nut counterclockwise (to increase tension) until clutch pedal will not return to normal position with ¾″ open end wrench.
2. Turn adjusting end nut clockwise (to reduce tension) approximately 1½ to 2 turns or until good pedal return is achieved.

All C Series Except Y & YX

The clutch pedal free travel is adjusted by loosening both the lock nuts and rotating the turnbuckle to shorten or lengthen the travel as required. Check the distance of free pedal motion to the following specifications:

⅞″ to 1″ on models G8, H8, J8, K8 and R8.

1¼″ to 1⅜″ on models T8 and V8.

1⅛″ to 1¼″ on all six-cylinder models.

C Series Y & YX

Loosen the lock nut on the clutch pedal stop screw and rotate the stop screw to lengthen or shorten the distance of free travel as required to bring it within the limits of 1¼″ to 1⅜″.

B Models Except DU & EU

Loosen the pedal adjusting screw lock nuts and turn the pedal adjusting screws until the pedal has 1″ to 1⅛″ free movement.

On C.O.E. and WFM models, the adjustment for free pedal movement is made by turning the swivel on the connecting rod between the pedal and operating lever.

B Models DU & EU

Remove the clevis that holds the adjusting rod to the operating lever. Loosen the nut and adjust the rod to obtain 1″ to 1⅛″ free pedal movement.

K & L Models

Loosen the lock nut on the clutch pedal stop screw and rotate the turnbuckle to shorten or lengthen travel as required. Check the free play and adjust as necessary to conform to the following specifications:

1½″ to 1¾″ on 700, 800 and 900 models.

1⅛″ to 1¼″ on all other models.

Fig. 1 Heavy duty clutch release bearing adjustment

HYDRAULIC CLUTCH

1959-63

A hydraulic master cylinder and slave cylinder replaces the mechanical linkage. The slave cylinder is connected to and operates the clutch release fork. The master cylinder and slave cylinder are serviced in a similar manner to a brake master cylinder.

When the master cylinder is installed on the dash panel and hydraulic line connected, connect the push rod end to the clutch pedal and adjust as follows:

Fig. 2 Hydraulic clutch actuation, 1959-63

Adjust master cylinder push rod so that there is .010″ free play between the push rod and master cylinder piston when the piston is in the fully returned position and when the clutch pedal, Fig. 2, is in its normal at rest position.

Adjustment

1. Inside the cab, adjust clutch pedal free play to ⅛″, which is equal to .010″ clearance between push rod and master cylinder piston.
2. On Light and Medium Duty models, at the slave cylinder, adjust clutch linkage free play at the clutch fork pivot pin to $\frac{3}{16}$″.
3. On Heavy Duty models, adjust the linkage free play at the clutch fork shaft lever to Dimension "A", Fig. 1 (see chart below).
4. Inside the cab, check clutch pedal reserve which should be a minimum of 1″. Pedal reserve is that portion of pedal travel remaining after free play and complete clutch disengagement. *Note: If there is not enough pedal reserve, bleed the clutch hydraulic system to make sure there is no air in the system.*

Clutch Free Play Specs.

The following applies to Heavy Duty models with flywheel housing and master cylinder diameter of 1⅛″.

Clutch Size	Slave Cylinder Diameter	"A", Fig. 1
14″①	1.12″	.069″
14″②	.94″	.093″
14″	.94″	.140″
13″③	1.12″	.093″
13″④	.94″	.125″
15″①	1.12″	.093″
15″②	.94″	.125″

①—All transmissions except Fuller R46.
②—Fuller R46 transmission.
③—All transmissions except Fuller R46 with two plate clutch.
④—Fuller R46 transmission with two plate clutch.

CLUTCH, REMOVE

C-1 & C-3 Models B, C, D, DU, EU, PW, R, T, V

1. Remove transmission.
2. Remove clutch housing pan.
3. Remove clutch release bearing.
4. Mark clutch cover and flywheel to assure proper balance when clutch is installed.
5. Remove clutch cover retaining screws and take out clutch and disc.

C-1 & C-3 Models F, G, H, J, K

1. Remove transmission floor cover.
2. Remove transmission.
3. Remove clutch housing pan.
4. Remove clutch release bearing.
5. Mark clutch cover and flywheel to assure proper balance when clutch is installed.
6. Remove clutch cover retaining screws and take out clutch and disc.

1952-56 Three & Four Speed C, D, DU, F, G, GM, PW

1. Remove transmission.
2. Remove clutch housing pan.
3. Remove clutch release bearing.
4. Mark clutch cover and flywheel to assure proper balance when clutch is installed.
5. Unfasten clutch cover from flywheel and take out clutch and disc.

B-3 & B-4 Models H, HH, J, KA, EU, R, T, V, Y

1. Remove all floor boards.
2. Remove transmission.
3. Remove clutch housing pan.
4. Remove clutch release bearing.
5. Disconnect booster brake control valve linkage at brake pedal, master cylinder and frame bracket. Then remove control valve.
6. Disconnect clutch release fork bracket at clutch housing.
7. Remove clutch release fork flange cap screws and pull release fork with pedal and bushings out of clutch housing far enough to provide clearance for clutch assembly to pass cross shaft clutch release fork.

1957-63

1. Remove the transmission.
2. Remove the clutch housing pan.
3. Remove clutch fork, bearing and sleeve assembly.
4. Mark clutch cover and flywheel to assure proper balance when clutch is installed.
5. Remove clutch cover retaining screws and pull the pressure plate clear of flywheel and, while supporting pressure plate, slide the disc from between flywheel and pressure plate. On some models it may be necessary to rotate the pressure plate to the point of maximum clearance. Then allow plate assembly to drop while tilting the top edge of the clutch cover back to clear the frame crossmember.

CLUTCH, INSTALL

All Models

When installing the clutch, coat the pilot bearing in the end of the crankshaft with wheel bearing grease. Clean the surfaces of the flywheel and pressure plate, making certain no oil or grease remains on these parts. Hold the cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the pilot bearing in the crankshaft. Bolt the clutch cover loosely to the flywheel, being sure that punch marks previously made are lined up.

To avoid distortion of the clutch cover, tighten the cover bolts a few turns each in progression until all are tight.

Guide the transmission into place, using care to see that the driven disc is not bent. Use a floor jack to support the transmission so that the clutch shaft may be guided through the driven disc safely. Finally, adjust the clutch pedal free travel.

Manual Shift Transmission Section

For Clark, Fuller, New Process, Spicer and Warner transmissions used on Dodge trucks, see the "name" chapter for service procedures and lubricant capacities.

TRANSMISSION, REPLACE

Three Speed Units

Disconnect propeller shaft, speedometer cable, speedometer pinion sleeve, gearshift control rods and hand brake cable. Remove transmission-to-clutch housing bolts and pull transmission straight back until clutch shaft clears clutch disc and release levers before lowering transmission out of truck. Do not disengage clutch or otherwise move clutch or clutch disc unless it is to be removed for service.

New Process 420

Shift gear shift lever into mesh with a drive gear. Disconnect universal joint and loosen yoke retaining nut. Disconnect brake and speedometer cables at transmission. Rotate gearshift lever retainer in a counterclockwise direction and pull up on lever at the same time. Do not lose spring or washer from lever. Remove transmission-to-clutch housing bolts and remove transmission from truck.

New Process 540, 541

Remove gearshift lever, floor mat and floor cover over transmission. Drop center bearing (if equipped). Place jack under transmission and unfasten transmission from clutch housing. Pull transmission with jack straight back about 6 inches. Then lower jack slightly. Move transmission with jack to the left so that clutch shaft will clear clutch housing. Lower transmission out of truck.

Clark 5 Speed Units

Remove floor mat and transmission access plate. Disconnect speedometer cable. On models with hand brake assembly, disconnect hand brake lever to hand brake rod or cable. Disconnect clutch control linkage at transmission bell housing. Disconnect propeller shaft and center bearing (if equipped).

If equipped with auxiliary transmission, disconnect transmission-to-auxiliary transmission companion flange. Place transmission jack under transmission and remove clutch housing-to-transmission cap screws. Move transmission back until clutch shaft is clear of clutch housing. Lower transmission from truck.

Spicer Auxiliary Units

Drain transmission lubricant. Shift each shaft to a forward position. Remove clevis pins and then place shafts to neutral position. Disconnect universal joint companion flange next to front of auxiliary transmission. Disconnect emergency brake rod and speedometer cable. *If it is difficult to disconnect speedometer cable, remove brake band.*

Mark sliding yoke and drive shaft with a center punch for proper installation. Position portable hydraulic jack under transmission and remove transmission support bolts. *Observe position of mounting components to assist in proper installation.* Lower transmission and pull sliding yoke from propeller shaft spline. Then remove transmission from truck.

DODGE 3 SPEED, 1952-58

Disassemble, Figs. 1, 2

1. Drain oil from transmission.
2. Remove cover assembly.
3. Remove nut at end of mainshaft and pull off flange and brake drum.
4. Remove speedometer drive pinion and oil seal.
5. Disconnect hand brake rod at band and remove horseshoe clip which anchors hand brake linkage to transmission.
6. Remove cap screws which hold brake support to transmission case and lift off support, oil seal and brake assembly.
7. Remove speedometer drive gear.
8. Remove main drive gear bearing retainer.
9. Pull mainshaft and gear assembly out of the rear of the case far enough to remove mainshaft rear bearing.
10. Lift mainshaft and gears out of case.
11. Slide low and reverse gear off mainshaft.
12. Remove clutch gear snap ring and slide off synchronizer and second speed gear assembly.
13. Remove countershaft lock plate.

Fig. 1 Dodge Three-speed synchromesh transmission with remote control, 1952-58

Fig. 2 Dodge Three-speed synchromesh transmission with remote control, 1952-58

14. Drive countershaft out of the rear end of the case, using a special arbor and soft hammer, allowing the gear cluster to drop to the bottom of the case.
15. Pull main drive gear out through front of case.
16. Remove main drive gear lock, lock and bearing.
17. Lift out countershaft gear cluster and thrust washers. By removing the arbor the bearings and spacer will be available for inspection.
18. Drive reverse idler gear shaft to the rear of case and lift out gear.

Assemble

The bearings on the rear end of the main drive gear and mainshaft are held in place by snap rings. Whenever these snap rings are removed, they should be replaced with new ones.

All assembly operations are performed in the reverse order of that given for disassembly. However, the following must be observed:

1. Countershaft end play should be held to .004" to .015". Install new thrust washers to achieve this result.
2. When inserting the bearing rollers in the ends of the countershaft gear, pack the ends of the gear with medium cup grease to hold the rollers in place.
3. The countershaft gear thrust washers should be placed in correct position after they have been coated with cup grease. At the front end of the transmission the small spacer is to be placed between the bronze washer and countershaft bearings.
4. When installing the main drive gear the lock nut must be securely tightened and staked at the notches provided on the shaft.
5. The synchronizer should be assembled so the slots of the stop ring engage the plates in the clutch gear sleeve.

1959-63 DODGE THREE SPEED

1. Referring to Fig. 3, remove transmission flange.
2. Remove extension housing.
3. Remove transmission cover.
4. Remove clutch shaft bearing retainer.
5. Grasp clutch shaft with hand and pull assembly out of case. *Be careful not to bind inner synchronizer ring on clutch teeth.*
6. With transmission in reverse, remove outer center bearing snap ring, using a hook or a flat blade, then partially remove mainshaft.
7. Cock mainshaft; then remove synchronizer sleeve, rings and 2-3 shift fork.
8. Remove clutch gear snap ring, using snap ring pliers. Slide clutch gear off end of mainshaft.
9. Slide second speed gear, stop ring and synchronizer spring off mainshaft.
10. Remove low-reverse sliding gear and shift fork as mainshaft is withdrawn from case.

Fig. 3 Dodge three speed transmission. 1961-63. Typical of 1959-60

11. Using a feeler gauge, check end play of cluster gear, which should be .004″ to .012″. This measurement will determine if new thrust washers are to be installed at reassembly.
12. Drive countershaft rearward and out of case. Remove key from end of shaft.
13. Lift cluster gear and thrust washers out of case. Dissassemble cluster gear by removing needle bearings (22 each end) and spacer.
14. Using a suitable drift, drive reverse idler gear shaft towards rear and out of case. Remove key from shaft.
15. Lift out reverse idler gear, thrust washers and needle bearings (22) out of case. Remove needle bearings from gear.

Assembly Notes

Reassembling the transmission is accomplished by reversing the disassembly procedure. However, observe the following:

1. When installing the reverse idler gear, have the bevelled ends of the gear teeth forward. Raise the idler gear slightly to align with shaft: then drive shaft into case, through thrust washer and gear, until end of shaft is approximately $\frac{1}{64}$″ below surface of case.
2. Cluster gear thrust washers are available in two sizes marked "A" and "B". Make a selection to give .004″ to .012″ total end play of cluster gear. Make sure tabs on thrust washers slide into grooves in case. Countershaft should be installed until approximately $\frac{1}{64}$″ below surface of case.
3. When installing mainshaft, have offset of low-reverse fork to rear. Engage fork in low-reverse gear, then position in case by shifting in reverse.
4. After sliding the synchronizer clutch gear on mainshaft and down against second speed gear, select a snap ring of the correct thickness and install. *Snap ring should eliminate end play and must be a snug fit.*
5. Check clearance between clutch gear and second speed gear, which should be .003″ to .008″. *End play in excess of .008″ will permit gear "jump out."*
6. After mainshaft is properly positioned, select a snap ring that will be a snug fit at the rear bearing.

GEARSHIFT, ADJUST

1961-63 Cross-Over Adjust

1. Place transmission in neutral.
2. Loosen 2-3 control rod swivel at shift lever, Fig. 4.
3. Move lever as necessary to align notches in both shift levers. Tighten control rod swivel nut.

1961-63 Control Rod Adjust

1. With transmission in neutral, loosen and back off both adjusting nuts at the control rod swivels, Fig. 4.
2. Move cross-over pin into engagement with 2-3 lever slot.

Fig. 4 Gearshift lever adjustments. 1961-63 three speed transmission

3. Without moving 2-3 shift lever, adjust and tighten 2-3 shift rod swivel nuts.
4. Move hand shift lever across neutral position to line up slots in lever hubs.
5. Without moving low-reverse lever position, adjust and tighten low-reverse rod swivel nuts securely.
6. When road testing, if one of these shifts is difficult, readjust low-reverse rod swivel nuts to eliminate difficulty.

1959-60 Cross-Over Adjust

Before making the cross-over adjustment, Fig. 5, the gearshift lever shaft must be in its normal fully returned position in neutral. Then proceed as follows:

1. Remove grease fitting from tube lever pin retainer. Rotate retainer until gearshift tube cross pin is exposed.
2. If a .040″ round feeler cannot be inserted between pin and bottom of slot, an adjustment at the gearshift tube lower support must be made as follows:
3. Loosen lower support screws slightly. Move support by tapping lightly with a plastic hammer. On vehicles with power steering, do not attempt to separate lower support after loosening.
4. Adjust support up or down as required to secure the necessary .040″ clearance.
5. Tighten support clamping screws to 150 *inch* lb. torque (90 *inch* lb. for power steering equipped vehicles).
6. Rotate tube-lever pin retainer to original position and install grease fitting securely. (Loss of fitting will result in loss of cross pin).

Fig. 5 Gearshift control rod adjustments. 1959-60 three speed transmission

7. Loosen 2nd-3rd control rod swivel at the shift lever.
8. Move lever as necessary to align the notches in both shift levers and tighten swivel lock nuts.

1959-60 Control Rod Adjust

After completing foregoing adjustments, be sure gearshift lever travels freely and equally up and down in either high or second gear position and low or reverse positions. Check the cross-over adjustments, Fig. 6, with the manual lever by making the cross-over from second-to-direct and from low-to-reverse. Cross-over must be free of interference. Transmission must be in neutral when making the following adjustments:

1. Loosen adjusting nuts at second-to-direct control rod swivel.
2. Turn both adjusting nuts in direction required to locate hand lever in horizontal plane.
3. Tighten adjusting nuts securely to swivel block.
4. Loosen adjusting nuts at low-to-reverse gearshift control rod swivel.
5. Position low-to-reverse gearshift lever in direct alignment (through center of swivel lock pin) with second-to-direct gearshift lever. Tighten adjusting nuts securely to swivel block.

Automatic Transmission Section

For service procedures on the Torqmatic, see the Allison transmission chapter. For the Loadflite, see the Warner automatic transmission chapter

LOADFLITE TRANSMISSION

Service Note for 1961-63 Inclined 6-Cyl. Engine

An adapter plate is used for installation of the Loadflite transmission on the inclined 6-cylinder engine. The adapter components consist of a mounting plate welded to the front face of the converter, an adapter plate bolted to the crankshaft flange, an adapter plate attached to the rear of the cylinder block, and a converter housing designed for attaching the transmission to the engine block adapter plate.

Transmission Repairs

For a detailed service procedure on this transmission see the *Loadflite Chapter* elsewhere in this manual. The following material outlines the procedure for removing the transmission and adjusting the push button control cable.

TRANSMISSION, REPLACE

1. Drain fluid from transmission.
2. Disconnect vacuum line at vacuum unit.
3. Disconnect speedometer cable at transmission.
4. Disconnect hand brake cable at bracket and remove clevis pin.

Fig. 1 Removing gearshift control cable. 1960-63

5. Disconnect gearshift control cable at transmission.
6. Disconnect two oil cooler lines and bracket.
7. Disconnect propeller shaft at transmission flange. *Wire end of propeller shaft to frame to permit transmission removal.*
8. Support transmission with suitable transmission lift.
9. Remove upper transmission case-to-converter housing cap screws. Install two pilot studs. Then remove lower cap screws.
10. Pull transmission rearward to disengage it from torque converter and remove the assembly from the truck.
11. Reverse the foregoing procedure to install the transmission.

PUSH BUTTON CONTROL CABLE, ADJUST

The importance of correct push button cable adjustment cannot be over-emphasized. Improper adjustment or a kinked cable can cause erratic shifting or possible front clutch failure. To make the adjustment, proceed as follows:

1960-63

1. Have a helper hold the "R" button firmly depressed.
2. Remove adjusting wheel lock screw, Fig. 1.
3. Back wheel off cable guide (counter-clockwise) until two or three threads are showing on guide behind wheel. *Important: Check wheel for free turning on the guide; remove any dirt or burrs in threads of cable guide that may interfere. Lubricate guide threads with a few drops of transmission fluid.*
4. Hold cable guide centered in hole in transmission case and apply only enough inward force to bottom assembly at the reverse detent. While holding cable bottomed, rotate adjusting wheel clockwise until it just contacts case squarely.
5. Turn wheel clockwise just enough to make the next adjustment hole in the wheel line up with the screw

Fig. 3 Torqmatic throttle linkage adjustment. 1959 models 500, 600

Fig. 4 Torqmatic throttle linkage adjustment. 1959 model 700

hole in case.

6. Counting this hole as No. 1, continue turning the wheel clockwise until the fifth hole lines up with the screw hole in the case.
7. Install lock screw and tighten to a torque of 30-50 inch lbs.

1959

1. Raise vehicle on hoist and drain 2 quarts of fluid from transmission.
2. Engage "L" push button.
3. Remove control cable lock clip.
4. Remove plug and locking screw.
5. With screwdriver inserted through plug hole, push gently against upward projecting portion of control cable adapter spring and pull outward on cable to remove cable from adapter housing.
6. Insert screwdriver into cable entrance hole in cable adapter housing and push cable adapter to limit of travel to the reverse detent position. Remove screwdriver.
7. Reinstall plug and locking screw in adapter housing.
8. Turn locking screw with screwdriver counter-clockwise until locking screw contacts adapter. Tighten locking screw firmly against adapter to cause adapter to bind against adapter housing. *Do not over-tighten screw as adapter housing may be damaged.*
9. Engage "R" button.
10. Hold cable in alignment with hole in adapter housing.
11. Push cable into housing until adapter spring engages groove in cable end.

Fig. 2 Torqmatic transmission range selector lever control cable. 1959-61

12. With a helper firmly holding the "R" button in at full travel position, carefully position cable housing at the midpoint of cable backlash.
13. While continuing to hold "R" button firmly, tighten cable adjusting clip screw securely, being careful not to move cable during tightening process.
14. With screwdriver, turn adapter locking screw clockwise to limit of travel. Tighten 10 to 16 inch lbs. In this position, locking screw seats against inner end of plug and prevents oil leakage at this point.

1956-58

1. "R" push button must be depressed and held all the way in during adjustment.
2. Loosen cable lock clip screw at transmission.
3. Push cable in until it stops; then release cable.
4. Tighten cable clip screw, making sure cable housing is not forced in or out during adjustment.
5. To check for proper operation, push the various buttons, return to "N" each time while checking starter operation. Engine should start only when "N" button is depressed.

Fig. 5 Torqmatic throttle linkage 1960-61 models C500, C600

Fig. 6 Torqmatic throttle linkage. 1960-61 models D500, D600

Fig. 7 Torqmatic throttle linkage. 1960-61 model D700

Fig. 8 Torqmatic throttle linkage. 1960-61 models C700, CT700

TORQMATIC TRANS.

A detailed service procedure on this transmission is carried in a separate chapter. Following are adjustment procedures for Dodge truck installations.

Range Selector Lever Linkage 1959-61

1. Referring to Fig. 2, place range selector lever in the "R" position.
2. Remove pin from clevis at transmission shift control lever.
3. Move clevis out of the way, then shift control lever all the way forward towards front of truck.
4. Push control cable into its sleeve until selector lever hits the "R" stop. In this position, hole in cable clevis should be aligned with hole in transmission shift control lever.
5. If alignment is not correct, loosen jam nut at clevis and turn clevis in or out until alignment is obtained and clevis pin can be installed easily.
6. Secure clevis pin with cotter pin and tighten jam nut.
7. Test operation of selector lever in all positions.

Fig. 9 Retarder linkage. 1959

Neutral Safety Switch, 1959-61

If necessary to adjust the switch so that the ignition remains off in all ranges except neutral first loosen the switch bracket screws and rotate the switch clockwise so that the starter circuit is closed when the lever is in neutral. Be sure to tighten mounting screws securely.

Throttle Linkage, 1959

Before attempting to make throttle linkage adjustments it is essential that the engine and carburetor be at peak operating efficiency. While the relative position of the linkage parts may vary slightly between truck models, adjustment and methods remain essentially the same. When making adjustments, refer to Figs. 3 and 4.

1. Remove throttle control spring from spring lever and spring clip.
2. At transmission, withdraw swivel from throttle control lever.
3. Remove carburetor air cleaner and note position of throttle valve.
4. With throttle valve closed, the throttle control lever stop should be in full contact against the throttle control bracket which is bolted to the engine left-hand cylinder head. Any necessary adjustment is made by loosening the swivel adjusting nuts on the throttle control rod and moving the rod or lever in the desired direction to obtain the condition mentioned above. After making adjustment, tighten adjustment nuts securely.
5. At the transmission, slowly move throttle control shift rod upwards and toward engine until travel of rod is stopped by the wide open throttle position lug on carburetor. *Do not move rod beyond this point.*
6. Holding rod in this position, rotate control lever (at transmission) clockwise until lever is firm against transmission internal stop. At this position, swivel pin should freely enter *lower hole* in transmission throttle control lever.
7. Any necessary adjustment is made by loosening jam and adjusting nuts and moving swivel pin into correct alignment. Finger tighten front and rear adjusting nuts against swivel.
8. Install swivel cotter pin and back off the swivel rear adjusting nut 6 turns. Then tighten front nut and jam nuts.
9. On engine side of dash panel, loosen lock nut of adjustable stop screw and turn in the adjustable stop several turns.
10. At the transmission, again move the control shift rod upwards and toward the engine until throttle control lever is firm against the transmission internal stop.
11. Holding shift rod firmly in this position, turn adjustable stop screw outward until it contacts throttle control bellcrank, then turn screw outward an additional ¼ turn. Lock stop screw in this position.
12. Reconnect throttle control spring and road test truck. If shift points are low shorten throttle control shift rod; if shift points are too high, lengthen rod.

Throttle Linkage, 1960-61

1. Referring to Figs. 5, 6, 7 and 8 for model being serviced, first remove throttle control return spring and governor floating arm spring. *Do not stretch or distort governor spring in any way as it will throw off the governor calibration.*
2. At transmission, remove transmission throttle control shift rod swivel cotter pin and withdraw swivel from TV lever on transmission.

Fig. 10 Retarder linkage. 1960-61

3. Remove carburetor air cleaner.
4. Place carburetor throttle lever in idle position.
5. Adjust throttle control rod so that accelerator control bellcrank stop is against bracket. Tighten nuts on throttle control rod.
6. Move carburetor throttle lever to wide open position.
7. On D700, Fig. 7, the wide open throttle stop bolt must be adjusted so that the bolt head contacts the bellcrank when the throttle is in wide open position.
8. With throttle control shaft pushed upwards until travel of rod is stopped by the wide open throttle stop, rotate the transmission throttle control lever (at transmission) forward until the TV lever is firm against the internal stop in the transmission. At this position the swivel pin should freely enter the lower hole in the transmission throttle valve (TV) control lever. Finger tighten front and rear adjusting nuts against swivel.
9. Back off swivel rear adjusting nut six turns and tighten nuts.
10. On all models except C700 and CT700, the through detent pedal stop (located on throttle control bellcrank) must be adjusted so that pedal forces cannot be applied to TV linkage. To do this, adjust stop so that it contacts the bracket bolted to the back of the engine at the same time the TV lever contacts the stop in the transmission. Then turn bolt ¼ turn further to eliminate any force being applied through the linkage from the stop in the transmission.
11. Reconnect throttle control spring and governor floating arm spring and road test vehicle.
12. After adjustment is complete, failure of the engine to return to the proper idle speed is an indication of too much length in the TV control rod. If engine idle is properly set at carburetor, this should be corrected by readjusting the TV linkage properly.

Retarder Linkage, 1959

1. Referring to Fig. 9, unhook transmission retarder control lever shaft return spring.
2. Loosen and back off lock nuts and upper and lower adjusting nuts at control rod swivel.
3. Place retarder valve in full applied position by pushing valve into body to limit of travel. Pull control rod downward until travel of rod is stopped by accelerator pedal making contact with its bracket and stop.
4. Run upper adjusting nut down to control rod swivel. Give nut two additional turns to lengthen control rod slightly. Tighten lower adjusting nut and both lock nuts. Replace spring.
5. Check adjustment by depressing the pedal. The retarder valve should be felt to bottom in the valve body just before the pedal bottoms. Check for full release of retarder valve and adjust if necessary.

Retarder Linkage, 1960-61

Referring to Fig. 10, adjust master cylinder push rod so that there is .010″ free play (measured at pedal pad approximately $\frac{1}{16}$″) between push rod and master cylinder piston, where piston is in its fully returned position. The system must be free of air and master cylinder filled to ½″ of top. Push rod on slave cylinder should travel ½″ for full retarder action.

Rear Axle Section

For Eaton and Timken (Rockwell) driving axles used on Dodge trucks, see the "name" chapters for service procedures and lubricant capacities

Fig. 1 Dodge differential carrier assembly used with semi-floating axle

Fig. 2 Removing axle shaft

DODGE SEMI-FLOATING AXLE

In this rear axle, Fig. 1, the drive pinion is mounted in two tapered roller bearings, preloaded by a spacer and shims. The drive pinion is positioned by an adjusting washer between the head of the pinion and the rear pinion bearing. The front bearing is held in place by a large washer and nut.

The differential is supported in the carrier by two tapered roller side bearings. These bearings are preloaded by two threaded ring nuts between the bearings and the pedestals. The differential assembly is positioned for proper ring gear and pinion backlash by varying the adjustment of these ring nuts. The differential case houses two side gears in mesh with two pinions mounted on a pinion shaft which is held in place by a lock pin. The differential side gears and pinions are backed by thrust washers. A thrust block through which the differential pinion shaft is fitted, controls the end thrust of the axle shafts.

DIFF. CARRIER ASSY

Any major repairs on the differential carrier assembly, such as replacing the ring gear and pinion, calls for most accurate and precise adjustments of the assembly. Therefore, if the necessary tools and equipment are not available to do a first rate job, the carrier assembly should be exchanged for a new one, or the work should be farmed out to the car dealer or an auto parts jobber who has the facilities to do the work properly. For the guidance of those who are equipped to do this type of work, refer to Fig. 1.

Remove & Replace

It is not necessary to remove the rear axle assembly for any normal repairs. The axle shafts and carrier assembly can easily be removed from the vehicle, leaving the rear axle housing in place.

1. Remove axle shafts as explained further on.
2. Disconnect rear universal joint and drop propeller shaft.
3. Use a suction gun to remove lubricant from carrier housing.
4. Remove attaching nuts and lift differential carrier from axle housing.

AXLE SHAFTS

Removal

1. Raise car and remove rear wheels. Pull off hub and drum assembly.
2. Block brake pedal to prevent it being depressed and disconnect brake lines at wheel cylinders.
3. Remove axle shaft key and remove brake support and dust shield.
4. Carefully remove shim pack from end of axle housing.
5. Pull out axle shaft, using a puller of the type shown in Fig. 2. *Do not use knock-off type puller as it may cause damage to bearings and thrust block in differential.*
6. If necessary, pull bearing from axle shaft.
7. Use a hook-type puller to remove inner oil seal from axle housing.
8. When pressing on a new bearing, make certain that bearing and axle shaft contacting surfaces are thoroughly clean so that bearing bottoms against axle shaft shoulder. Tapered portion of bearing must face axle shaft threads.

Installation

Where original axle shafts and bearings are used, start measurement of end play with original shim packs, after recording thickness of each. When either or both the axle shaft and bearing is replaced, use shim packs totaling .040″ on each side. Shims are available in thicknesses of .005, .0125, .015 and .030″.

1. Install inner seal with a suitable driver.
2. Starting at one end of the axle housing, install a .040″ shim pack on flange studs.
3. Working from same side of axle housing, lubricate shaft bearing with multi-purpose gear lube and install axle shaft.
4. Install bearing cup, using tool shown in Fig. 3 or equivalent.
5. Install brake support, lockwashers and nuts. Tighten nuts to 30-35 ft. lbs.
6. Working from opposite side of axle housing, lubricate bearing and install other axle shaft until it contacts axle shaft thrust block.
7. With a soft mallet, lightly tap end of axle shaft against the thrust block. This will force opposite axle shaft bearing to seat in its cup.
8. Install bearing cup with tool shown in Fig. 3 or equivalent. Cup must be driven gently into position until axle shaft end play just disappears without preloading bearing. Bearing cup will protrude slightly beyond face of axle housing flange.
9. With tool, Fig. 3, held firmly against bearing cup, insert feeler gauge between axle housing flange and face of tool to measure clearance.
10. To determine thickness of shim pack required, add a minimum of .013″ to the feeler gauge reading on 1957 and later models (.005″ on earlier cars). Compare the thickness of this shim pack with the thickness of the opposite pack. If the difference in the thickness of the shim pack exceeds .020″, divide the difference between both axle shaft bearings to center the axle shafts and the thrust block. Equal thickness of shims on both axle shafts is necessary to maintain the centralized position of the axle shaft thrust block.

Fig. 3 Installing axle shaft bearing cup

11. Position shim packs on flange studs and drive bearing cups in until tool, Fig. 3, bottoms on shim packs.
12. Install new outer oil seals on brake support plates with lip of seal toward center of vehicle.
13. Insert a suitable sleeve tool in outer seal to protect seal when brake support is installed.
14. Install dust shield and brake support. Tighten attaching nuts to 30-35 ft. lbs.
15. Install wheels, hub and drum.

DODGE FULL-FLOATING AXLES

In these axles, Figs. 4 and 5, the servicing procedure is fundamentally the same as outlined for semi-floating axles with exception of removing axle shafts, servicing the barrel type differential case shown in Fig. 4, and the ring gear thrust block adjustment.

Axle Shaft, Replace

1. Remove axle shaft flange nuts.
2. Install puller screws in the threaded holes provided, then tighten the screws to loosen the shaft. If threaded holes are not provided, tap the flange with a soft-faced hammer to loosen the shaft.

Fig. 6 Removing case cap lock pin from barrel type differential case

3. When installing the shaft, use a new gasket and tighten the flange nuts to 30-35 ft-lbs torque.

Barrel Type Diff. Case

1. After the differential assembly is removed from the carrier, remove the drive gear thrust block from the ring gear side of the carrier housing. Break the weld on the lock nut and remove the screw from the housing.
2. Remove differential case cap lock pins by center punching and drilling out the pins, Fig. 6.
3. Heat the case (not the cap) by playing a torch around the outside of the cap. Keep the flame moving to assure even heating. While heating, touch the case with a piece of ordinary solder from time to time. When the solder just starts to melt, the case is heated to the proper temperature.
4. Unscrew the cap, using the tool shown in Fig. 7. To loosen the cap, strike the handle of the tool with a hammer, then quickly unscrew the cap. Remove side gear and thrust washer.
5. Remove differential pinion shaft lock pins by driving them out of the case, Fig. 8.

Reassembly

1. Install a thrust washer on side gear hub, then place gear and washer in case.
2. Drive long pinion shaft into case as shown in Fig. 9.
3. Place thrust washer on one of the pinions, then position washer and pinion on end of long shaft that protrudes through case. Tap shaft through pinion until it is flush with bottom of pinion.
4. Insert pinion shaft thrust block into axle shaft thrust block with long pinion shaft holes aligned, and prick punched faces toward short pinion holes. Position this assembly in case, then drive pinion shaft through the blocks just flush with bottom of blocks.
5. Install next thrust washer and pinion. Drive shaft through washer and pinion into its final position. Make sure lock pin holes are lined up.

42. Pinion bearing spacer

6. Drive one of short pinion shafts into either of the remaining holes until it protrudes about $\frac{1}{16}''$ inside of case with lock pin hole aligned with lock pin hole in case.
7. Position a thrust washer and pinion on end of shaft, then drive shaft through pinion and into hole in pinion shaft block. Install other short pinion shaft, thrust washer and pinion in same manner.
8. Install three new locking pins, driving them through to a depth of $\frac{1}{16}''$ below machined face of case. Peen case to hold lock pins in case.
9. Install a thrust washer on remaining side gear hub, then place gear and washer into case.
10. Heat the case to recommended temperature (see disassembly) and install the cap. Tighten the cap securely, Fig. 7. Drill new $\frac{1}{4}''$ holes through case and cap and install new locking pins.
11. Install drive gear thrust block before installing differential into carrier. Thread thrust screw through carrier, having one thread visible inside carrier. Hold block on screw with heavy grease.

Ring Gear Thrust Block

Run the thrust block screw in about four turns to force the block against the back face of the ring gear. Install lock nut on screw. Back out screw $\frac{1}{8}$ of a turn to provide .006 to .008″ clearance, then tighten lock nut. Weld nut to carrier in two spots.

Steering Gear Section

GEMMER WORM & ROLLER STEERING GEAR

Light & Medium Duty Trucks

In this type steering gear, Fig. 1, the worm is integral with the steering shaft and is supported on each end by opposed tapered roller bearings. The triple tooth roller is attached to the roller shaft by means of a steel shaft. Two needle bearing assemblies are installed between this shaft and the roller. (Some light duty models have a two tooth roller shaft).

The roller shaft is mounted in the steering gear housing on two needle bearing assemblies which are pressed into the housing. The housing cover is attached to the housing by four cap screws. An adjustment screw, mounted in the cover, controls roller shaft end play and worm and roller mesh adjustment.

The steering wheel and roller shaft arm (pitman arm) are splined to the steering shaft and roller shaft respectively. Both the pitman arm and steering wheel have master splines to insure correct installation.

Worm End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the four cover screws about ⅛".
3. Use a knife to separate the top shim, passing the blade all the way around between the shims, being careful not to damage the remaining shims.
4. Remove one shim at a time between inspections to remove the end play.
5. The adjustment is correct when there is no end play and no stiffness in the steering gear throughout the complete range of its travel.

Roller Shaft End Play, Adjust

1. Turn the steering gear to either extreme and back off ⅛ of a turn.
2. Gripping the pitman arm at the hub, the roller shaft should rotate freely without a particle of end play.
3. If end play exists, adjust as required by means of the roller shaft adjusting screw in the side cover.
4. Be sure to tighten the lock nut securely and inspect for end play and free rotation throughout the entire range of steering gear travel.

Worm & Roller Mesh, Adjust

1. Loosen the roller shaft adjusting screw lock nut.
2. With the steering gear in its central position (drag link disconnected) tighten the roller shaft adjusting screw just enough to remove play between the roller shaft roller tooth and worm.
3. Check this by the amount of play felt at the pitman arm. It is better to leave a slight amount of play at this point than to tighten too much.
4. If tightened beyond the point where the lash is removed, serious results will occur which will cause poor steering operation.

Fig. 1 Gemmer worm and roller steering gear. Light and medium duty trucks

Fig. 2 Ross cam and twin lever steering gear. Heavy duty trucks

Fig. 3 Gemmer worm and sector steering gear. Power Wagon and Route Vans

Fig. 6 Recirculating ball-nut type steering gear assembly

5. Tighten the adjusting screw lock nut.

ROSS CAM & LEVER STEERING GEAR

Heavy Duty Trucks

This steering gear, Fig. 2, is the cam and twin lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove, causing the lever arm to rotate the lever shaft. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and the cam where most of the steering action occurs.

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the lock nut adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are .002″, .003″ and .010″ thickness.
4. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim. If necessary, remove or replace shims until the adjustment is correct.

Fig. 4 Recirculating ball-nut type steering gear cross shaft

Fig. 5 Recirculating ball-nut type steering gear worm shaft

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then, starting from this point, count the number of turns required to reach end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but a slight drag should be felt in the mid-position only.
3. After proper adjustment is secured, tighten the lock nut and give the gear a final check for binding.

GEMMER WORM & SECTOR STEERING GEAR

Power Wagon & Route Vans

In this type steering gear, Fig. 3, the worm is integral with the steering shaft and is supported on each end by opposed tapered roller bearings. The triple tooth sector and shaft is mounted in the steering gear housing in two bushings which

are pressed in the housing. The housing cover is attached to the housing by cap screws. An adjustment screw, mounted in the cover, controls sector shaft end play and worm and sector mesh adjustment.

Adjustments

Adjustment of this type steering gear is accomplished in the same manner as outlined for the Gemmer Worm & Roller type.

RECIRCULATING BALL STEERING GEAR

A worm and recirculating ball type steering gear is used with the manual steering gear system, Figs. 4, 5 and 6. The steering worm shaft is a "stub" type and is connected to the steering shaft with a universal joint type coupling. The worm shaft is supported on each end by ball type thrust bearings. The sector shaft rotates in two needle bearings in the steering housing and a needle bearing in the housing cover.

Two adjustments are required: worm bearing pre-load, and ball nut and sector gear mesh. These adjustments must be made carefully and in the order given to ensure satisfactory results.

Worm Bearing Pre-load

1. Disconnect steering gear arm from sector shaft.
2. Loosen sector shaft adjusting screw lock nut and back out adjusting screw approximately two turns. This relieves the load imposed by the closely meshed ball nut and sector gear teeth.
3. Turn steering wheel two complete turns from straight-ahead position. *Do not turn steering wheel hard against stops in gear when steering gear arm is disconnected as internal damage might result.*
4. Remove horn button and spring. With an inch-lb. torque wrench and socket on steering wheel nut, rotate wheel at least one turn (toward straight-ahead position). The torque required to keep the wheel moving should be 5-9 inch lbs.
5. To adjust the pre-load, loosen the lock nut on the large adjuster nut which threads into the housing. Turn the adjuster clockwise to increase pre-load or counter-clockwise to decrease the pre-load.

Ball Nut and Sector Gear Mesh

The sector shaft adjusting screw, located in the housing cover, raises or lowers the shaft to provide the proper mesh load between the tapered teeth of the sector gear and tapered teeth of the ball nut. This adjustment is made only after the proper worm bearing pre-load has been obtained.

1. Turn steering wheel gently from one stop all the way to the other, carefully counting the number of turns. Then turn the wheel back exactly half way, to the center position.
2. Turn the sector shaft adjusting screw lockwise to take out all lash between the gear teeth, then tighten the adjusting screw lock nut.
3. Turn steering wheel about ¼ turn away from center and using an inch-lb. torque wrench and socket on the steering wheel nut, check the torque required to pull the steering wheel through the high spot (center) position. The torque reading should be between 5-11 inch-lbs. more than worm bearing preload. This represents the total of the worm bearing preload and the steering gear mesh preload. Readjust if necessary to obtain proper torque. Total torque reading should not exceed 18 inch lbs.
4. After the adjustments have been completed, align front wheels in the straight-ahead position. Then install steering arm on sector shaft and tighten retaining nut to 85 ft. lbs.

① Long mark represents top dead center (TDC) and each succeeding mark represents respectively 3°, 5°, 7° and 9° before TDC.
② Two-barrel carburetor 8°BTDC, four-barrel carburetor 10°BTDC.
③ Cylinder numbering (front to rear): Right bank 1-2-3-4, left bank 5-6-7-8.
④ ECW engines 5°BTDC. ECR and ECY 10°BTDC.
⑤ ECR-Y Engines 10°BTDC. ECW Engines 8°BTDC for conventional or overdrive transmissions and 10°BTDC for Fordomatic.
⑥ For city stop and go, parcel delivery, light loads and low engine speeds, use Autolite BFT-3; for all other service use BTF-31.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

⑤—With 11000 lb. axle.
⑥—With 15000 lb. axle.

ENGINE IDENTIFICATION—Ford Truck Identification Plate located on inside of truck cab or on firewall. To identify engine and transmission, refer to code tables. Engine Code Table is given below; see transmission section of this manual for Transmission Code Table. Information stamped on plate represents only the equipment on the truck when it was shipped from the factory.

Engine Section

ENGINE, REPLACE

1952
8-239 Conventional Trucks

1. Drain radiator and crankcase.
2. Remove hood, air cleaner and battery.
3. Disconnect heater hoses at engine.
4. Disconnect generator wires, temperature sending unit wire, oil pressure sending unit wire, flexible fuel line, choke wire, throttle linkage, vacuum hose and starter cable at starter.
5. Remove upper radiator hoses.
6. Remove fan and belt, generator and belt.
7. Remove radiator.
8. Disconnect ignition switch-to-coil wire, muffler inlet pipe and clutch pedal retracting spring.
9. Remove road draft tube.
10. Place support under transmission to prevent it dropping out of line when engine is removed.
11. Install engine lift hook and take up slack with a hoist.
12. Remove engine front bolts, and transmission-to-flywheel housing bolts.
13. Pull engine away from transmission and lift it from engine compartment.
14. Reverse the foregoing procedure to install the engine.

1952
8-239 Cab-Over-Engine Trucks

1. Drain crankcase and cooling system.
2. Remove hood, air cleaner, flexible tube, floor pan over engine and dash panel.
3. Remove oil filter lines.
4. Remove either front wheel.
5. Remove grille assembly.
6. Disconnect radiator and its support.
7. Disconnect generator wires, ignition switch-to-coil wire, temperature sending unit wire, oil pressure sending unit wire, vacuum hose at intake manifold, starter cable at starter, throttle linkage, choke wire, heater hoses, flexible fuel line, muffler inlet pipe and clutch release bearing spring.
8. Remove engine front support bolts.
9. Remove generator, carburetor, crankcase inlet pipe and fuel pump.
10. Install engine lift hook and take up slack with hoist.
11. Unfasten transmission from flywheel housing.
12. Move engine away from transmission and out of the engine compartment.
13. Reverse the foregoing procedure to install the engine.

1952-53 Parcel Delivery Trucks

1. Drain crankcase and cooling system.
2. Remove hood and radiator support bar.

Engine oiling diagram. 6-223 engine

3. Disconnect upper radiator hose.
4. Remove fan shroud from radiator and lean shroud against engine.
5. Remove radiator support and radiator and lift out fan shroud.
6. Remove engine compartment rear cover.
7. Open engine compartment front cover and attach hook at left corner near hinge to keep it open.
8. Remove weatherstrip retaining panel at rear edge of engine compartment rear cover.
9. Remove air cleaner and flexible tube.
10. Disconnect generator wires, ignition switch-to-coil wire, temperature sending unit wire, oil pressure sending unit wire, vacuum hose at intake manifold, starter cable at starter, throttle linkage, choke wire, heater hoses, flexible fuel line, muffler inlet pipe, clutch release bearing spring, and hand brake cable where it is clipped to the transmission.
11. Fasten engine lift bracket to cylinder head.
12. Project portable floor crane through right-hand door. Connect crane chain to lift bracket and take up engine weight. Remove engine front support bolts. Unfasten transmission from flywheel housing.
13. Move engine far enough forward to clear transmission mainshaft. Then lift engine and move it through the door.
14. Reverse the foregoing procedure to install the engine.

1952 6-215 Conventional Trucks

1. Drain cooling system.
2. Remove hood.
3. Disconnect battery ground cable at engine, temperature sending unit wire, oil pressure sending unit wire, primary coil wire and starter cable at starter.
4. Disconnect generator wires, windshield wiper vacuum hose, choke control, hand throttle control, and accelerator rod and spring at carburetor.
5. Remove air cleaner and tape carburetor opening closed.
6. Disconnect radiator upper hose at engine, lower hose at radiator and heater hose at engine.
7. Remove fan and belt.
8. Remove fan shroud and radiator.
9. Disconnect muffler inlet pipe.
10. Shut off fuel valve at tank and disconnect flexible fuel line to pump.
11. *If engine and transmission are to be removed as an assembly, disconnect drive shaft and pull it out of transmission extension. Remove transmission extension support bolts.*
12. If the engine is to be removed without the transmission, remove the transmission retaining bolts and disconnect the clutch return spring. Support transmission with a jack.
13. Remove engine front support nuts.
14. Install engine lift and with a hoist, carefully lift engine out of chassis.
15. Reverse the foregoing procedure to install the engine.

1953 (Except Super Duty Jobs)

1. Drain cooling system.
2. Drain crankcase.
3. Remove hood.
4. Remove fan and belt.
5. Remove radiator and shroud.
6. *On trucks equipped with air compressor, open air reservoir drain*

cock. Loosen fitting at reservoir inlet line. Disconnect air line and clip at front of engine and lay line against engine side compartment.

7. Remove air cleaner and tape carburetor air horn closed.
8. Disconnect vacuum hose at manifold, hand throttle control, choke cable, accelerator rod and spring at carburetor.
9. Disconnect temperature sending unit wire, oil pressure sending unit wire, ignition coil primary wire, generator wires, flexible fuel line at fuel pump, muffler inlet pipe at exhaust manifold, clutch release lever retracting spring, starter cable at starter and battery ground strap at engine.
10. Remove starter and install engine lifting sling.
11. Remove flywheel housing-to-engine bolts, and remove flywheel housing lower cover.
12. Remove engine front support bolts.
13. Take up weight of engine with a hoist. Support transmission with a jack and move the engine forward to separate the clutch from the transmission input shaft. Then lift engine from chassis.
14. Reverse the foregoing procedure to install the engine.

1953-56 Cab Forward Trucks

1. Drain cooling system.
2. Drain crankcase.
3. Disconnect throttle return spring.
4. Remove floor mat, battery cover and floor pan. Disconnect one battery cable to break circuit.
5. Disconnect coil primary wire and ground wire at coil mounting bracket.
6. Remove screws retaining loom clip, tail light wire clip and speedometer cable and move wires and speedometer cable out of the way.
7. Remove distributor cap and rotor.
8. Remove fan and belt.
9. Remove air cleaner and tape carburetor air horn closed.
10. Disconnect radiator and heater hoses.
11. Remove upper and center grille sheet metal, radiator, shroud and radiator-to-front fender apron supports.
12. Disconnect hand throttle control, choke control and accelerator linkage.
13. Remove vacuum hose at intake manifold or vacuum pump inlet.
14. *On trucks equipped with air compressor, vent air compressor drain cock. Remove compressor. Remove clip retaining air line to front end of right hand cylinder bank, loosen fitting at reservoir end of line and lay the line back against engine side compartment.*
15. Remove temperature sending unit wire and generator wires.
16. Remove oil level dipstick.
17. Remove engine front support nuts and washers.

Engine lubrication. V8-401, 477, 534 engines

Engine lubrication. V8-239, 256, 272, 292 engines

18. Disconnect flexible line at fuel pump.
19. Close off main fuel line to prevent loss of fuel.
20. Disconnect muffler inlet pipe.
21. Remove flywheel housing lower cover.
22. Unfasten flywheel housing from engine.
23. Disconnect starter cable and remove starter.
24. Install engine lifting sling. Place wood block between jack and oil pan.
25. Raise engine slightly and remove front support bolts and rubber pad.
26. Raise engine and lift it out of chassis.
27. Reverse the foregoing procedure to install the engine.

Overhead Valve Six (typical)

1953-59 Fordomatic Trucks

To remove the engine from Fordomatic equipped vehicles, perform the steps outlined for the appropriate truck in the preceding paragraphs. Then perform the following operations.

1. Disconnect transmission oil-to-water cooler inlet and outlet tubes.
2. Remove upper screws retaining converter housing to engine.
3. Remove converter housing-to-engine lower screws.
4. Remove converter housing lower access cover and turn the flywheel until the flywheel drive plate is in position so that the three bolts can be removed. Turn the flywheel 180° and remove the other three bolts.
5. Install engine lifting sling and remove engine in usual manner.

1954-59 Parcel Delivery

1. Drain the cooling system and crankcase.
2. Remove the driver's seat assembly, the master cylinder inspection cover, and the steering column cover plates.
3. Disconnect the accelerator pedal at the accelerator assembly, and the wires from the dimmer switch.
4. Remove the left wheel house panel and the center floor plate.
5. Remove the screws fastening the right side of the engine rear cover panel to the right wheel house panel.
6. Remove the bolts and nuts retaining the rear flange of the engine rear cover to the removable frame crossmember and the center floor plate front bracket. Wedge the right and left frame gussets open so the rear flange of the engine rear cover plate will clear the slots.
7. Remove the frame crossmember.
8. Remove the accelerator bracket assembly, accelerator return spring and the carburetor.
9. Disconnect exhaust manifold at the muffler inlet pipe and remove the inlet pipe to engine bracket bolt.
10. Disconnect generator wires at the generator.
11. Disconnect the flexible fuel line at the fuel tank.
12. Disconnect engine temperature and oil pressure sending unit wires at the sending units.
13. Disconnect the coil and resistor primary wires.
14. Disconnect the battery ground cable at the battery.
15. Remove the starter.
16. Remove the fan blade and bracket as an assembly and remove the radiator.
17. Remove the engine right and left front support to frame bracket bolts.
18. Remove the flywheel or converter housing cover.
19. Remove the flywheel housing or converter housing to engine block and engine rear plate retaining bolts.
20. Remove engine right and left rear support capscrews.
21. Remove the engine crankcase breather tube.
22. Support the engine with a jack.
23. On Fordomatic equipped vehicles, disconnect the oil cooler hoses at the engine.
24. Drain the transmission and remove the filler tube.
25. Install the drain plugs in the torque converter.
26. Remove the engine from the vehicle.
27. Reverse the foregoing procedure to install the engine.

1957-59 Tilt Cab (Except Super Duty Jobs)

1. Release cab lock and tilt cab forward.
2. Drain cooling system and the crankcase.
3. Remove clamps holding the throttle, choke, and accelerator cables, and the heater hoses to the radiator.
4. Remove the fan assembly and the drive belts and remove the radiator and shroud as an assembly.
5. Remove the air cleaner and disconnect the heater hoses from the engine.
6. On trucks equipped with air compressor, open the air reservoir drain cock and disconnect the air line at the front of the engine and place the line against the frame side rail.
7. Disconnect the fuel line.
8. Disconnect oil pressure and water temperature sending unit wires at the sending units.
9. Disconnect the throttle control, choke control, and the accelerator cables at the carburetor, and the vacuum brake hose (if equipped).
10. Remove the clutch release lever retracting spring and the crankcase ventilator tube extension.
11. Disconnect primary wires at the ignition coil and resistor, and disconnect the generator wires.

Engine lubrication. V8-332 engine

12. Remove the starter.
13. Disconnect the radiator supply tank hose at the tank.
14. Remove the oil filler pipe assembly clamp at the water supply tank bracket.
15. Remove the exhaust manifolds from the muffler inlet pipes.
16. Support the transmission and remove the flywheel housing inspection cover and the flywheel housing to engine retaining bolts.
17. Remove the engine front support insulator bolts.
18. Attach engine lifting hooks and sling.
19. Remove the engine and lower the engine on blocks and remove the right exhaust manifold.
20. Reverse the foregoing procedure to install the engine.

1958-59 Super Duty Conventional Trucks

1. Remove hood and cross braces.
2. Drain cooling system and crankcase.
3. Disconnect battery ground strap and all carburetor linkage, wires, and fuel lines from engine.
4. Remove fan, radiator and shroud.
5. On trucks with conventional brakes, disconnect vacuum assist brake line from intake manifold.
6. On power steering jobs, disconnect power steering oil lines.
7. On trucks with air compressor, loosen outlet line at air compressor and allow air to escape; then disconnect the line. Disconnect air compressor governor line at compressor.
8. Disconnect wiring harness at alternator.
9. Remove oil filter and crankcase ventilator tube.
10. Disconnect exhaust pipes at exhaust manifolds.
11. Place jack under front bumper at right side and raise truck.
12. Remove starter shield and starter; then lower truck and remove jack.
13. Unfasten engine mountings and lift engine from truck.
14. Reverse removal procedure to install engine.

1958-59 Super Duty Tilt Cab Trucks

1. Drain cooling system and crankcase.
2. Disconnect battery ground cable and remove air cleaner.
3. Remove oil level dipstick.
4. Disconnect radiator supply tube at front thermostat housing. Remove radiator supply tank bracket bolts. Disconnect cab latch anti-rattle springs; then remove bracket and tank.
5. Disconnect carburetor linkage, wires and fuel lines from engine.
6. Remove drive belts, oil filter, starter and shield, and crankcase ventilator tube.
7. Remove radiator and fan.
8. On conventional brake jobs, disconnect vacuum assist brake line at intake manifold.
9. On power steering jobs, disconnect pump lines.
10. On trucks with air compressor, loosen outlet line at compressor and allow air to escape; then disconnect line. Disconnect air compressor governor line at compressor. Remove compressor belt and pulley.
11. Disconnect exhaust pipes from manifolds.
12. Remove oil pan.
13. Support transmission with jack. Remove engine mounting bolts and lift engine from truck.
14. Reverse removal procedure to install engine.

1960-63 B & F Series With 6-Cyl. Engine

1. Remove hood, radiator and shroud, air cleaner, fan and pulley, starter, flywheel housing inspection cover or converter housing lower access cover.
2. Disconnect usual items such as carburetor linkage, wires and cables, fuel and vacuum lines, hoses, etc. from engine.
3. Remove upper right and lower left engine rear plate-to-flywheel housing retaining bolt.
4. Disconnect exhaust manifold from exhaust pipe.
5. If equipped with transmission oil cooler, disconnect cooler lines at engine.
6. Remove remaining flywheel housing retaining bolts.
7. Attach lifting rig to engine.
8. Remove engine front support bolts.
9. Lift engine out of chassis.

1960-63 P Series With 6-223 Engine

1. Remove driver's seat, master cylinder inspection cover and steering column cover plates.
2. Remove left wheel house panel and center floor plate.
3. Disconnect right side of engine rear cover panel from right wheel house panel.
4. Disconnect rear flange of rear engine cover from removable frame crossmember and center floor plate front bracket.
5. Remove air cleaner tube but leave air cleaner attached to engine cover.
6. Wedge right and left frame gussets so rear flange of engine rear cover plate will clear slots. Then remove cover plate.
7. Remove carburetor, starter, fan and bracket, radiator, engine front bolts, flywheel or converter housing cover, and crankcase ventilator tube.
8. Unfasten flywheel housing or converter housing-to-engine attaching bolts.
9. Disconnect usual items such as carburetor linkage, wires and cables, fuel and vacuum lines, hoses, etc. from engine.
10. Loosen engine rear support capscrews.
11. On automatic transmission jobs, disconnect oil cooler lines at engine. Remove filler tube and drain transmission. Raise rear of transmission with jack.
12. Attach engine lifting rig and swing rear of engine toward right about 30° and manually lift rear of engine to clear engine compartment. Then remove engine through right door.

1960-63 B, F & T Series With 292, 302, 332 Engines

1. Remove hood, air cleaner, radiator and shroud, fan, starter, flywheel housing inspection cover or converter housing front cover and lower cover.
2. Disconnect usual items such as carburetor linkage, wires and cables, fuel and vacuum lines, hoses, etc. from engine.
3. If equipped with air compressor,

open air reservoir drain cock and disconnect compressor lines.
4. Disconnect exhaust manifolds from exhaust pipes.
5. Remove engine front support bolts.
6. If equipped with power steering, disconnect hydraulic lines from bracket on frame and, after draining fluid from reservoir, disconnect fluid lines from pump.
7. Remove flywheel housing retaining bolts.
8. On automatic transmission jobs, disconnect converter from flywheel and remove converter housing-to-cylinder block retaining bolts. Remove transmission cover plate with accelerator assembly. Disconnect oil cooler lines.
9. Attach engine lifting rig.
10. Support transmission with jack and remove remaining flywheel or converter housing bolts.
11. Lift engine out of chassis.

1960-63 F & T Series With 401, 477, 534 Engines

1. Remove hood and cross braces, air cleaner, fan, radiator and shroud, oil filter, crankcase ventilator tube, starter, engine front support bolts and flywheel housing dust cover.
2. Disconnect carburetor linkage, wires and cables, fuel and vacuum lines, hoses, etc. from engine.
3. On trucks with brake booster, disconnect vacuum assist brake line at intake manifold.
4. On trucks with power steering, drain oil from reservoir and disconnect fluid lines from pump and from frame side rail.
5. On trucks with air compressor, loosen outlet line at compressor and allow air to escape before disconnecting line. Disconnect governor air line at compressor.
6. Disconnect exhaust manifolds from exhaust pipes.
7. Install lifting rig, position jack under transmission and remove flywheel-to-engine bolts. Then lift engine out of chassis.

1960-63 C Series With 292, 302, 332 Engines

1. Tilt cab forward.
2. Remove fan, belts, radiator and shroud, air cleaner and starter.
3. Disconnect carburetor linkage, wires and cables, fuel and vacuum lines, hoses, etc. from engine.
4. If equipped with air compressor, open air reservoir drain cock. Disconnect air lines at front of engine and place against frame side rail.
5. Unfasten exhaust manifolds from exhaust pipes.
6. Support transmission and remove flywheel housing cover and flywheel housing-to-engine attaching bolts.
7. Remove engine front support bolts.
8. Attach lifting rig and remove engine from chassis.

1960-63 C Series With 401, 477, 534 Engines

1. Tilt cab forward.
2. Remove air cleaner, oil level dipstick, oil filter, starter, crankcase ventilator tube, radiator, fan and oil pan.
3. Disconnect carburetor linkage, wires and cables, fuel and vacuum lines, hoses, etc. from engine.
4. On trucks with brake booster, disconnect vacuum assist brake line at intake manifold.
5. On trucks with power steering, drain oil from reservoir and disconnect fluid lines from pump. Loosen pump and remove drive belt.
6. On trucks with air compressor, loosen outlet line at compressor and allow air to escape before disconnecting line. Disconnect governor air line at compressor. Remove compressor pulley and drive belt.
7. Disconnect exhaust manifolds from exhaust pipes.
8. Remove flywheel housing dust cover and flywheel-to-engine bolts.
9. Disconnect parking brake clevis pin and engine front mounts at frame crossmember.
10. Attach lifting rig.
11. Raise engine approximately one inch and support transmission with jack.
12. Remove engine from chassis.

CYLINDER HEAD, REPLACE

1952-53 L-Head Six Conventional Trucks

1. Drain cooling system.
2. Remove air cleaner.
3. Disconnect upper radiator hose.
4. Disconnect temperature unit wire.
5. On 1952-53, remove screw from distributor vacuum line clamp on forward left corner of cylinder head.
6. Remove spark plugs.
7. Disconnect heater hose.
8. Remove screw from manifold air baffle on right-hand side of head.
9. Remove cylinder head.
10. Install the head in the reverse order of removal and tighten head bolts in the sequence shown in Fig. 1.

1952-53 L-Head Six Cab-Over-Engine Trucks

1. Drain cooling system.
2. Disconnect upper water hose.
3. Remove engine compartment cover.
4. Disconnect temperature sending unit wire.
5. Remove screw from manifold air baffle on right-hand side of cylinder head.
6. Remove spark plugs.
7. Disconnect heater hose.
8. Remove cylinder head.
9. Install cylinder head and tighten bolts in sequence shown in Fig. 1.

1952-53 8-239

1. On 1952 Cab-Over-Engine models, remove transmission cover plate, right-hand seat, floor mat and engine cover panel. On 1953 Cab Forward models, remove engine rear cover.
2. Drain cooling system.

Fig. 1 Cylinder head tightening. L-head Six

Fig. 2 Cylinder head tightening. L-head 8-239 engine

Fig. 3 Cylinder head tightening. Overhead Valve Six

Fig. 4 Cylinder head tightening sequence. Overhead valve V8s

3. If left-hand cylinder head is to be removed, disconnect and fold back generator wires and ignition wires. Disconnect oil filter lines.
4. On 1952-53 models, when removing right-hand head, remove coil bracket mounting screws and allow coil to hang from distributor.
5. Disconnect heater hose.
6. Disconnect radiator hose.
7. Disconnect battery ground strap.
8. Remove spark plugs.
9. Remove one head bolt at each end and install guide studs in these holes.
10. Remove remaining bolts and lift off head.
11. Install heads in reverse order and tighten bolts in the sequence shown in Fig. 2.

1952-57 6-215 & 6-223 Removal

1. Drain cooling system and disconnect radiator and heater hose at cylinder head outlet elbow.
2. Disconnect windshield wiper vacuum line from manifold.
3. Remove air cleaner. (On Parcel Delivery models, remove air cleaner tube.)
4. Remove valve chamber cover.
5. Disconnect fuel line at fuel pump

and carburetor and distributor vacuum line at distributor and carburetor.
6. Remove spark plugs.
7. Disconnect coil from head and allow coil to hang from distributor.
8. Disconnect engine temperature sending unit wire.
9. Remove fan assembly.
10. Remove capscrew and clip from No. 6 rocker arm support bracket.
11. Pull oil feed line out of bracket and block.
12. Loosen all rocker arm adjusting screws to remove valve spring load from rocker arms.
13. Slide rocker arms away from push rods and remove rods. The rocker arms at each end of the 6-215 engine cannot be moved so they should be left in place.
14. Tag the push rods so they can be reinstalled in the same place from which they were removed.
15. Unfasten the manifold and pull it away from the head, allowing it to be supported by the muffler inlet pipe.
16. Remove all cylinder head bolts. Install guide studs, and lift the head assembly off the engine.
17. Install head in reverse order of removal and tighten bolts in the sequence shown in Fig. 3 to the torque given in the *Engine Tightening Chart.*

1954-55 8-239 & 8-256

1. To remove the cylinder heads, drain cooling system and disconnect upper radiator hose.
2. Disconnect ground cable from right-hand cylinder head.
3. Remove air cleaner and tape carburetor air horn closed.
4. Disconnect choke control cable at carburetor.
5. Disconnect windshield wiper vacuum line.
6. Disconnect accelerator linkage.
7. Disconnect vacuum line at distributor (and governor vacuum lines on 256 engines).
8. Disconnect wires from coil.
9. Disconnect fuel line at carburetor.
10. Disconnect vacuum line at intake manifold.
11. Remove exhaust crossover pipe.
12. Remove spark plugs.
13. Disconnect muffler inlet pipe from right-hand exhaust manifold and remove manifolds.
14. Disconnect water by-pass tube from water outlet.
15. Disconnect fuel and vacuum lines from fuel pump.
16. Remove intake manifold, carburetor and ignition coil as a unit.
17. Remove rocker arm cover.
18. Loosen rocker arm adjusting screws to relieve valve spring tension.
19. Remove rocker arm assembly and oil baffle plates.
20. Remove valve push rods, keeping them in their order of removal for proper reinstallation.
21. Disconnect wire from temperature sending unit.
22. Remove ignition harness bracket from right-hand head.
23. Remove generator bracket rear bolt.
24. Remove exhaust manifolds.
25. It is strongly recommended that the cylinder head holding fixture shown in Fig. 5 be used as it has been designed so all work operations may be performed with the fixture in place. *Thus, the machined surfaces are being protected from being scratched or marred which would require extensive repair work to prevent a gasket leak.*
26. Remove head bolts and lift off head and gasket.
27. Install heads in reverse order of removal and tighten bolts in the sequence shown in Fig. 4 to the torque given in the *Engine Tightening Chart.*

1952-57 V8-272, 279, 302, 317 & 332

Removal

1. Drain cooling system.
2. Remove rocker arm cover.
3. Remove exhaust manifolds, spark plugs and intake manifold.
4. Remove valve chamber cover.
5. Remove ignition harness bracket from rear corner of right head.
6. Remove oil level indicator tube from crankcase.
7. Disconnect temperature sending unit wire from left head.
8. Remove air compressor (if so equipped).
9. Release spring tension on rocker arms by loosening adjusting screws, then remove rocker arm assembly and oil baffle plates.
10. On ECR-272, 302 and 332 engines, remove exhaust valve caps, being sure to identify them for proper installation.
11. Remove and identify valve push rods so they can be replaced in their original positions.
12. Remove cylinder head bolts.
13. Install suitable holding fixture, Fig. 5, and lift head off block.
14. Install heads in reverse order of removal and tighten bolts in the sequence shown in Fig. 4 to the torque given in the *Engine Tightening Chart.*

1958-59 Six-Cyl.

1. Remove air cleaner and tape carburetor air horn closed.
2. Disconnect hoses, wires, carburetor linkage, fuel and vacuum lines as necessary for removal of cylinder head.
3. Remove coil, distributor cap and spark plugs.
4. Remove rocker arm cover.
5. Remove capscrew and bracket from No. 6 valve rocker arm support. Pull oil inlet line out of support and out of engine.
6. Remove capscrews from No. 1 valve rocker arm support and remove oil outlet line and bracket.
7. Loosen all rocker arm adjusting screws to relieve valve spring tension from rocker arms; then remove rocker arm shaft assembly.
8. Remove all push rods.
9. Unfasten and pull manifold away from cylinder head.
10. Unfasten and lift off cylinder head.
11. Install head in reverse order of removal and tighten bolts in the sequence shown in Fig. 3 to the torque given in the *Engine Tightening Chart.*

1958-59 V8-272, 292, 302, 332

1. Drain cooling system and remove air cleaner.
2. Remove rocker arm covers.
3. Remove exhaust manifolds and spark plugs.
4. Remove intake manifold and carburetor as a unit.
5. Remove push rod cover.
6. Remove air compressor (if used).
7. On right cylinder head, remove ignition harness bracket.
8. On 272 and 292 engines, remove generator bracket rear bolt.
9. Release spring tension on valve rocker arms by loosening adjusting screws; then remove rocker arm shafts.
10. On 302 and 332 engines, remove oil baffle plates and exhaust valve caps. Identify caps for proper installation.
11. Remove and identify push rods for proper installation.
12. Unfasten and remove cylinder heads.
13. Install heads in reverse order of removal and tighten bolts in the sequence shown in Fig. 4 to the torque given in the *Engine Tightening Chart.*

Service Note

On 302 and 332 engines, be sure valve rocker arm shaft supports are installed so that the large O.D. end of the center hole in the support is to the top. There is a difference in height when the supports are installed upside down.

1958-59 V8-401, 477, 534

1. Drain cooling system.
2. Remove air cleaner, intake manifold and rocker arm covers.
3. Disconnect exhaust pipes at manifolds.
4. Release tension of valve springs by loosening adjusting screws; then remove rocker arm shafts and oil baffle plate. *Because five cylinder head bolts also serve as pedestals for the rocker arm shafts, each time the rocker shafts are removed the cylinder head gasket must be replaced.*
5. Remove push rods and identify for proper installation.
6. Unfasten and remove cylinder heads.
7. Install heads in reverse order of removal and tighten bolts in the sequence shown in Fig. 4 to the torque given in the *Engine Tightening Chart.*

1960-63 Six Cyl.

1. Remove air cleaner and tape carburetor air horn closed.
2. Disconnect hoses, wires, carburetor linkage, fuel and vacuum lines as necessary for removal of cylinder head.

3. Remove coil and spark plugs.
4. Remove distributor cap and high tension wires as a unit.
5. Remove rocker arm shaft assembly.
6. Remove push rods, keeping them in proper sequence so they may be returned to original locations.
7. Unfasten and pull manifold away from engine.
8. Unfasten and remove cylinder head.
9. Install head in reverse order of removal and tighten bolts in the sequence shown in Fig. 3 to the torque given in the *Engine Tightening Chart.*

1960-63 V8-292, 302, 332 Engines

1. Remove intake manifold and carburetor as a unit.
2. Remove rocker arm covers.
3. Remove exhaust manifolds and spark plugs.
4. Remove air compressor (if so equipped).
5. On right head, remove ignition harness bracket, and generator bracket rear bolt.
6. On left head of 292 engine, disconnect temperature sending unit wire at unit.
7. Disconnect engine ground strap.
8. Release spring tension on valve rocker arms by loosening adjusting screws; then remove rocker arm shaft assembly.
9. On Heavy-Duty engines, remove and identify exhaust valve caps for proper installation.
10. Remove and tag push rods so they may be installed in original location.
11. Unfasten and remove cylinder head.
12. Install heads in reverse order of removal and tighten bolts in the sequence shown in Fig. 4 to the torque given in the *Engine Tightening Chart.*

1960-63 V8-401, 477, 534 Engines

1. Remove intake manifold.
2. Remove push rod cover and rocker arm covers.
3. Disconnect muffler inlet pipes at exhaust manifolds.
4. Release spring tension on rocker arms by loosening adjusting screws.
5. Remove rocker arm shaft and oil baffle plate. *Because five cylinder head bolts also serve as pedestals for the rocker arm shaft, each time the rocker arm assembly is removed, a new cylinder head gasket must be installed.*
6. Remove push rods, keeping them in proper sequence so they may be installed in original location.
7. Remove remaining cylinder head bolts and lift off head.
8. Install heads in the reverse order of removal and tighten bolts in the sequence shown in Fig. 4 to the torque given in the *Engine Tightening Chart.*

VALVES, ADJUST

Overhead Valve Engines

Prior to 1957, rocker arm adjusting screws are provided with a lock nut. Starting with 1957 engines self-locking adjusting screws are used.

If the cylinder head or rocker arm assemblies have been removed and installed, a preliminary (cold) valve lash adjustment should be made before starting the engine. If the adjustment is made in connection with an engine tune-up, the valve lash adjustment should be made with the engine at operating temperature.

To make the "hot" adjustment, operate the engine for a minimum of 30 minutes at a fast idle to stabilize engine temperatures. With the engine idling, check the valve lash with the proper feeler gauge between valve stem and rocker arm. Adjust the lash by means of the adjusting screw to the clearance given in the *Valve Specifications* table.

To make the "cold" adjustment, first turn over the engine to bring No. 1 piston up on its compression stroke, which will be indicated by the TDC mark on the vibration damper. Then proceed as follows:

1952-63 Six Cylinder

Make two chalk marks on the vibration damper. Space the marks approximately 120 degrees apart ⅓ of circumference) so that with the timing mark the damper is divided into three equal parts. Adjust the valves for No. 1 cylinder. Repeat this procedure for the remaining set of valves, turning the crankshaft ⅓ turn at a time in the direction of normal rotation, while adjusting the valves in the firing order sequence, which is 153624.

1952-63 V8

Make three chalk marks on the vibration damper. Space the marks 90 degrees apart (¼ of circumference) so that with the timing mark the damper is divided into four equal parts. Rotate the crankshaft until No. 1 piston is near TDC at the end of the compression stroke and adjust the following valves:

No. 1 intake and exhaust
No. 2 intake
No. 4 exhaust
No. 5 exhaust
No. 7 intake

Rotate the crankshaft 180 degrees (½ turn) which puts No. 4 piston on TDC. Then adjust the following valves:

No. 4 intake
No. 5 intake
No. 6 exhaust
No. 8 exhaust

Rotate the crankshaft 270 degrees (¾ turn), which puts No. 3 piston on TDC.

Fig. 5 Valve adjustment. 1952-53 L-Head V8s

Then adjust the following valves:

No. 2 exhaust
No. 3 intake and exhaust
No. 6 intake
No. 7 exhaust
No. 8 intake

1952-53 V8 Engines L-Head

Since there are no means of adjusting valves when these engines are assembled, this operation must be performed after the valves have been refaced and before assembling the valve guides and springs.

To check the valve clearance, turn over the engine until the valve being checked is fully closed. Slip a feeler gauge between the valve stem and the valve lifter, Fig. 5. If the clearance is not according to that given in the *Valve Specifications* table, remove the valve and grind the end of the valve stem, being sure that the valve stem is ground perfectly square.

VALVES, REMOVE

Overhead Valves V8

With the cylinder head removed as outlined previously, use a suitable valve spring compressor, Fig. 6, to compress each spring. Remove the valve locks and sleeve, tapping the sleeve with a soft hammer if necessary. Remove the neoprene sleeve from the valve stem and release the pressure on the spring. Remove the spring compressor and lift off the valve retainer sleeve, retainer, spring and valve. Repeat for the remaining valves. Keep the valves and related parts together so they may be installed in their respective positions if found in satisfactory condition.

Six Cylinder

After taking off the head as outlined previously, proceed as follows:

1. Remove capscrews retaining rocker shaft brackets to head and remove shaft assembly.
2. Clean carbon out of combustion chambers before removing valves.
3. Compress valve springs with a suitable spring compressor, remove valve stem locks and release the springs. Remove sleeve, valve spring cap re-

Fig. 6 Use of valve spring compressor to remove and install valves

Fig. 8 Removing valve guide retainer. 1952-53 V8 L-Head

tainer, spring and valve. Discard intake valve seals.

4. Place valves in a board with numbered holes so they can be replaced in their original positions upon reassembly.

1952-53 V8 L-Head

The valve, guide, spring and retainer are assembled and installed in the engine as one unit, Fig. 7.

To remove the assembly, insert a bar type valve lifter through the valve spring and to the flange on the lower end of the valve guide, Fig. 8. Using the top of the valve chamber as a fulcrum, pull down on the valve guide and withdraw the guide retainer. Then with the valve lifter tool, push the assembly up and remove it from above.

When replacing valve and guide assemblies in the block, be sure to have the joint in the valve guide at *right angles* to the camshaft.

Fig. 7 L-Head valve. 1952-53 V8

VALVES, GRIND

All Models

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{1}{32}$", otherwise the valve must be replaced, Fig. 9.

Inspect the valve seats in the head for cracks, burns, pits, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition.

VALVE GUIDES

Overhead Valve Engines

Valve guides in these engines are an integral part of the head and, therefore, cannot be removed. For service, guides can be reamed oversize to accommodate one of three service valves with oversize stems (.003", .015" and .030").

Check the valve stem clearance of each valve (after cleaning) in its respective valve guide. If the clearance exceeds the service limits of .004" on the intake or .005" on the exhaust, ream the valve guides to accommodate the next oversize diameter valve.

① ECW and ECY engines.
② ECR engines.

1952-53 V8 L-Head

See *Valves, Remove* inasmuch as the valve, guide, spring and retainer are assembled and installed in the engine as one unit.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 10. If the assembled height is greater than the

Fig. 9 Reface valve requirements

dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is $\frac{1}{16}''$, and since the acceptable valve head margin is approximately $\frac{1}{16}''$ to $\frac{3}{32}''$, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, *the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.*

VALVE SPRING TESTING

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 11, and according to the specifications given in the *Valve Data Chart.* If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

ROCKER ARMS

All Overhead Valve Engines

To disassemble the rocker arms, remove cotter pins from each end of the shaft and remove the flat washers and spring washers. Slide rocker arms, springs and supports off shaft, being sure to identify all parts so they can be assembled in the same position.

If it is necessary to remove the plugs from each end of the shaft, drill or pierce one plug, then insert a steel rod through the plug and knock out the plug on the opposite end. Working from the open end, knock out the remaining plug.

Assemble the rocker arms and related parts as indicated by Figs. 12 to 16.

Fig. 10 Checking valve spring installed height

Fig. 11 Checking valve spring pressure

VALVE ROTATORS

Overhead Valve V8s

The successful operation of the free type valve assembly depends entirely upon proper installation. The procedure is as follows:

1. Check valve guides after cleaning out deposits and if bell-mouthed or worn so that the clearance is over .020", install new valve guides.
2. Reface valve seats and check with dial indicator for runout—which should not exceed .002".
3. Inspect valves to be certain that valve seats and parts have not been nicked in handling and that valves are not warped or burnt.

Service Note

If free valves are used with hydraulic lifters, bleed oil out of hydraulic units by inserting a brass wire through the tube to open the check valve and then press down on the plunger until it bottoms. Install valve and lifter and check clearance—which should be .040"-.090".

Fig. 17 Details of exhaust valve rotator. Overhead valve V8 engines

Check clearance between end of valve stem and inside of cap. This clearance can readily be checked after the parts are assembled in the engine by turning the engine over until the valve is off the seat and can be rotated freely by thumb and forefinger in the lifted position. In this free position the actual clearance can be measured by locating an indicator on the valve head and noting the reading when the valve is moved vertically. This clearance can be .0002" providing the valve turns freely but not over .004" maximum vertical movement, Fig. 17. If vertical movement exceeds .004", polish the open end of the cap against a piece of fine emery cloth to bring vertical movement of valve to specified clearance. If vertical movement is less than .0002", grind off the end of the valve stem to provide above clearance.

VALVE SEAT INSERTS

(Not Used on 6 Cyl. & 1954-55 8-239)

The tool shown in Fig. 18 is used to remove these inserts. If necessary to

Fig. 12 Layout of rocker arm parts. 1954-55 8-239 and 8-256 engines

remove an insert when the puller is not available, use a drill which is smaller in diameter than the width of the insert and drill two holes at opposite sides, but not all the way through. Then cut through the undrilled portion with a sharp chisel and remove the two pieces.

To install an insert, chill it in "dry ice" for at least 30 minutes to allow the metal to contract. Then press the insert into its counterbore in the cylinder block, using extreme care to see that it goes in straight.

When necessary to reface inserts, a high speed grinding stone or lapping tool must be used as they cannot be ground by the conventional hand grinding method.

VALVE LIFTERS

All Models Except Below

Valve lifters are of the barrel type and can be lifted out of the engine after removing push rods on overhead valve engines or the valves on L-head engines.

1954-55 8-239 & 8-256,

Valve lifters in these engines are of the mushroom type which makes it necessary to remove the camshaft in order to take out the lifters. After dropping the oil pan, fasten the lifters with wire or spring-type clothes pins so they will not interfere with the camshaft as it is being withdrawn. After removing the camshaft, the lifters may be unfastened and taken out through the bottom of the block.

TIMING GEAR COVER

1952 6-254

To remove the cover, remove radiator, vibration damper and the two screws holding the oil pan to the gear cover. Unfasten the cover from the block and take it off.

1953 6-254

To remove the cover, take off the radiator and vibration damper. Remove the two screws that secure the oil pan to the front cover. Remove engine front support nuts and raise the front end of the engine far enough for the front cover to clear the supports. Remove the cover retaining screws. Loosen the oil pan retaining screws slightly. Then remove the front cover from the dowels by tapping along the edge with a soft-faced hammer.

1952-53 8-239

To remove the cover, take off the fan and distributor. Then unfasten the cover from the block and lift it off.

1952-57 Six Cyl.

To remove the cover, take off radiator, fan and generator belts, fan assembly, vibration damper, oil pan and engine front support bolts. Raise the engine far enough for the cover to clear the front support bolts. On 6-223 engine, remove the front support. On all engines, unfasten the cover from the block and lift it off.

1952-55 8-279 & 8-317

To remove the cover, drain crankcase and remove oil pan and vibration damper. Support the front of the engine on a jack. Remove engine front support bolts and raise the front of the engine enough so that the front support bracket clears the front mounting bolts. Remove the screws from the support bracket and cover. Remove the bracket, cover and gasket.

1954-55 8-239 & 8-256

To remove the cover, remove the radiator and oil pan. Remove fan belt, pulley, fan and generator. Support front of engine with a jack. Remove the crankshaft pulley and engine front support bracket. Disconnect water by-pass tube at water pump. Remove fuel pump. Unfasten the cover from the cylinder block, pull the cover forward until it clears the crankshaft, then remove the cover.

1956-57 8-272, 302, 332

1. Remove oil pan and radiator.
2. Remove drive belts, fan and vibration damper.
3. On 272 engine, remove fuel pump.
4. Support front of engine with a jack.
5. Remove engine front support nuts and raise engine so front support bracket clears front mount bolts.
6. Remove front support bracket, front cover and gasket.

1958-59 Six Cyl.

To remove the cover, drain the cooling system and oil pan. Remove radiator, vibration damper and oil pan. Remove cover screws and take off cover and gasket.

1958-59 V8-272, 292, 302, 332

To remove cover, drain cooling system and oil pan. Remove radiator, oil level dipstick and oil pan. Remove drive belts, fan, vibration damper, and on 272 and 292 engines, remove fuel pump.

Support front of engine, Remove front mounting bolts and raise engine slightly. Remove bolts retaining front support bracket to timing case cover and remove bracket. Then remove remaining cover bolts and lift off cover and crankshaft oil slinger.

1958-59 V8-401, 477, 534

To remove cover, drain cooling system and oil pan. Remove fan, shroud and radiator. Remove alternator, power steering pump and air compressor drive belts. Remove air compressor idler pulley and disconnect alternator adjusting arm at cylinder front cover. Remove water pump, vibration damper, engine front support bracket and oil level dipstick. Remove front cover and oil pan.

1961-63 6-262 Engine

1. Remove radiator, fan, spacer, drive belts and pulley.
2. Remove vibration damper, fuel pump and water pump.
3. Remove flywheel housing inspection cover and oil pan.
4. Remove timing gear cover.

1960-63 6-223 Engine

1. Drain cooling system and crankcase.
2. Remove radiator and vibration damper.
3. Remove water pump, oil level dipstick, crankcase ventilator tube, flywheel housing inspection cover and oil pan.
4. Unfasten and remove front cover.

1960-63 V8-292 Engine

1. Drain cooling system and crankcase.
2. On P-Series trucks, remove hood, grille, headlamps, parking lamps, wind deflector and hood lower weatherstrip as a unit.
3. Remove radiator, vibration damper and fuel pump.
4. Remove engine front support bolts and raise front of engine slightly.
5. Unfasten front support bracket from cylinder front cover and remove bracket.
6. Unfasten and remove front cover.

1960-63 V8-302, 332 Engines

1. Drain cooling system and crankcase.
2. Remove radiator and vibration damper.
3. Remove fuel pump (302 engine).
4. Support front of engine, remove support bolts and raise engine slightly.
5. Unfasten front support bracket from front cover and remove bracket.
6. Unfasten and remove front cover.

1960-63 V8-401, 477, 534

1. Drain cooling system and crankcase.
2. Remove fan, shroud, radiator, alternator, power steering pump and air compressor drive belts.
3. On F and T Series, lift front of engine about one inch with a floor jack to allow removal of damper.
4. Remove air compressor idler pulley and disconnect alternator adjusting arm at front cover.
5. Remove water pump, engine front support bracket and oil level dipstick.
6. Remove front cover.

TIMING GEARS

1952-53 L-Head Six

The bolt-on type camshaft gear, Fig. 19, is secured to the camshaft gear hub by four screws which are locked with retaining tabs. The mounting holes are spaced to make it impossible to install the gear incorrectly. The camshaft gear hub is aligned by a key and pressed on the shaft. The pressed on type gear is pressed on the camshaft and is located on the shaft by a key.

After removing the gear cover as outlined previously, follow the instructions given here that apply to the type of installation being worked on.

Fig. 19 Valve timing. 1952-53 L-Head Sixes

Fig. 20 Valve timing. 1952-53 L-Head V8s

Fig. 21 Valve timing. 302 and 332 engines. Typical of 401, 477, 534 engines

Fig. 22 Valve timing. 6-223 engine

If the gear is the bolt-on type, bend the lock ring tabs away from the capscrews. Remove the capscrews and lock plate. Remove the gear from the camshaft and use a suitable puller to remove the hub from the camshaft.

If the gear is pressed on, core holes are provided on either side of the hub to facilitate removal. Install a puller in these holes and pull off the gear.

When the timing gear is installed, be sure the timing marks are aligned as shown in Fig. 19. After installing the gear, check the backlash which should be between .002″ and .003″.

Oversize camshaft gears are available for service. Install the next oversize gear when excessive backlash exists between the crankshaft and camshaft gears.

1952-53 L-Head V8 Engines

The camshaft gear is secured to the camshaft by four screws which are kept from coming loose by a lock ring. The mounting holes are spaced to make it impossible to install the gear incorrectly.

After removing the gear cover as outlined previously, rotate the crankshaft until the timing marks line up, Fig. 20. Remove the retaining screws and remove the camshaft gear.

When the timing gear is installed, be sure the timing marks on the camshaft gear and crankshaft gear line up.

Check gear backlash which should be .002″ to .003″. Oversize gears are available for service replacement if backlash is excessive.

1961-63 6-262 Engine

Caution: When the timing gears are removed from the engine, do not rotate the camshaft or crankshaft as interference may occur between the crankshaft and cam lobes.

When installing timing gears, mesh the timing mark between two of the camshaft gear teeth with the timing mark on one of the crank gear teeth.

1956-63 V8-302 to 534

The camshaft gear is a slip-on fit and is retained on the end of the camshaft by a lock plate and three cap screws.

Fig. 23 Valve timing on V8-239, 256, 272, 292 engines. The punch link type chain was used on some 1954 engines

To remove, drain cooling system and crankcase. Remove oil pan, radiator, water pump and front cover. Crank engine until timing marks are aligned as shown in Fig. 21. Remove cap screws and lock plate and take off camshaft gear.

When installing the gear, be sure to have the timing marks lined up as shown.

TIMING CHAIN

1952-63 Overhead Valve Six

Before removing the camshaft sprocket, align the timing marks as shown in Fig. 22. Remove the camshaft sprocket retaining bolt and washer. Slide the camshaft sprocket, chain and crankshaft sprocket forward until the camshaft sprocket comes off the camshaft.

To install, place the chain over the crankshaft sprocket and insert the camshaft sprocket in the chain so the timing marks of both sprockets are positioned as shown in Fig. 22. Align the key in the camshaft with the camshaft sprocket keyway and slide the assembly into position. Recheck the timing. Install the washer and retaining bolt and tighten the bolt to 45-50 lb. ft. torque.

1954-63 8-239, 256, 292, 272

The camshaft sprocket is a slip-on fit and is keyed to the end of the camshaft. The camshaft sprocket, fuel pump eccentric counterweight, eccentric, spacing washer and lock washer are retained on the camshaft by a capscrew.

When installing, position camshaft sprocket and chain on the camshaft. Be sure the timing marks on both sprockets are properly aligned as shown in Fig. 23. Install the parts removed and tighten the retaining capscrew to 35-45 lb. ft. torque.

1952-55 8-279 & 8-317

The camshaft sprocket is bolted to the camshaft. It can be placed on the shaft in only one position since the bolt holes are unequally spaced.

Before removing the chain and camshaft sprocket, align the timing marks as shown in Fig. 24. Then remove the camshaft thrust piston and spring. Bend down the retaining tabs on the lock plate and remove the capscrews retaining the sprocket to the camshaft. Slide the sprocket off the shaft and remove the chain.

When installing, *be sure the notch on the camshaft hub is aligned with the timing mark on the crankshaft sprocket.* Place the camshaft sprocket in the chain and place the chain over the crankshaft sprocket with the timing marks on the sprockets aligned as shown in Fig. 24. When installed, tighten the capscrews to a torque of 15-18 lb. ft.

Fig. 24 Valve timing. 1952-55 8-279 and 8-317 engines

CAMSHAFT & BEARINGS

1952-63 Overhead Valve Engines

The camshaft is supported on five insert type bearings (4 on 6-cyl.) in the cylinder block. On 8-279 and 8-317 engines, camshaft end thrust is controlled by oil pressure against the end of the thrust piston in the forward end of the camshaft. The piston bears against a boss on the inside of the front cover.

On all other V8s, as well as 6-cylinder engines, camshaft end thrust is controlled by a thrust plate mounted on the cylinder block at the forward end of the camshaft.

To remove the camshaft, take off the front cover, cylinder heads and push rods as outlined previously. On engines with mushroom type valve lifters, raise the lifters and fasten them with wire or spring-type clothes pins so that they will not interfere with the camshaft as it is being withdrawn. Of course, if barrel type lifters are used, merely remove them from their bores after removing the push rods.

If it becomes necessary to replace the camshaft bearings as determined by a bearing leak detector test, the engine will have to be removed from the chassis and the bearings removed and installed with special equipment designed especially for the purpose.

1952-53 L-Head Engines

To remove the camshaft, take off the front cover, cylinder heads and remove the valves. Lift out the valve lifters, or if equipped with mushroom type lifters, tie them up with wire or spring-type clothes pins so they will not interfere with the camshaft as it is being withdrawn.

If it becomes necessary to replace camshaft bearings as determined by a bearing leak detector test, remove the engine from the chassis and remove and replace the bearings with the special equipment designed for the purpose.

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, use a ridge reamer to remove any ridge that may have formed on the cylinder wall at the top of the piston ring travel. Cutting the ridge before the piston is removed will avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod cap and push the piston and rod out through the top of the bore. Use care to prevent the rod from nicking crankshaft journals. Identify the connecting rods (original rods are marked) when removing them so they may be installed in their original cylinder.

PISTON & ROD, ASSEMBLE

1952-63 Overhead Valve V8s

Lubricate all parts with light engine oil. Position the connecting rod in the

piston and push the pin into place, Figs. 25 and 26. Insert new piston pin retainers by spiralling them into the piston with the fingers. Do not use pliers.

1952-53 L-Head V8s

When pistons and rods are assembled, the numbered side of the rods must be towards the outside of the engine. In other words, left bank rod numbers must be towards the left side of the engine and right bank rod numbers toward the right side of the engine. If the installation is correct, the rod squirt holes will be on the front side of left bank rods and the rear side of right bank rods.

All 6 Cyl.

Piston heads are marked for location on the forward side. Rods and caps are numbered on the same side as the piston they serve.

PISTONS, REPLACE

If the pistons are to be re-used with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring. File the broken end to a sharp, square edge and use it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands.* Pistons showing scuffed or scored skirts should be discarded for new ones. Examine the ring lands carefully for cracks. If in the least bit doubtful, the piston should be scrapped.

PISTON RINGS, REPLACE

New rings should be assembled on the piston according to the instructions furnished by the ring manufacturer. Always use standard size rings in cylinder bores that are *standard at the bottom, regardless of the amount of cylinder wear.*

When new rings are installed without reboring cylinders the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

Fig. 25 Correct assembly of pistons and rods. 1954-63 V8 (except 401, 477, 534)

Fig. 26 Assembly of pistons and rods. 1958-63 V8-401, 477, 534

Fig. 27 Checking bearing clearance with Plastigage

If the piston grooves are worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with the lower end of the piston. Then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of the rings carefully with a smooth file.

PISTON PINS, REPLACE

It is recommended procedure to replace pistons pins whenever new rings are installed. Pins that have been relatively quiet when the old rings were in service may be noisy after new rings are installed.

Use a suitable reamer to ream the piston for oversize pins. The pins are retained by snap rings, one located at each end of the pin. When installing the retainers, make sure each one enters the groove in the piston pin boss.

ROD BEARINGS, REPLACE

These bearings are of the insert type, selectively fitted, and available for service replacement in standard and undersizes for use on crankshaft journals that have been reground.

If inspection reveals badly worn or scored bearings, they should be replaced. Bearings may be removed by simply taking off the bearing caps and slipping the old ones out and the new ones in. The installation of new bearings must be closely checked to maintain the proper clearance between the crankshaft and bearing surface. A convenient and accurate method for checking bearing clearance is with the use of Plastigage, which is available at any auto parts jobber.

Place the string-like plastic material so it extends the full width of the bearing, Fig. 27. Install the bearing and cap and tighten the nuts to the recommended torque. Then loosen the nuts and carefully remove the cap and bearing. The widest portion of the Plastigage is then measured with the scale on the Plastigage envelope. Fig. 27. The graduation on the envelope corresponding to the thickness of the Plastigage gives the bearing clearance in thousandths of an inch.

MAIN BEARINGS, REPLACE

Like the rod bearings, main bearings are of the insert type and are removed, replaced and checked for clearance with Plastigage in the same manner.

CRANKSHAFT END PLAY

End play of the crankshaft is controlled by flanges on the rear main bearing on all L-Head engines and by the flanges on the center main bearing on overhead valve engines. Through normal wear, end play will seldom become excessive but whenever new bearings are fitted, check the end play carefully by forcing the crankshaft forward as far as possible with a pry bar. Then, using a dial indicator or feeler gauge, force the crankshaft back and note the end play. If the end play is excessive, the bearing flanges may be dressed down if the clearance is insufficient. If end play is too great, install a new bearing.

CRANKSHAFT OIL SEAL, REPLACE

Overhead Valve V8s

The rear main bearing cap contains the lower half of the crankshaft journal oil seal and the cap itself is sealed to the block. It is recommended that the tool shown in Fig. 28 or its equivalent be used to form the seal in both the block and bearing cap.

With the crankshaft removed, take out the rear main bearing inserts and pry the seals from the cap and block. Clean the seal grooves thoroughly.

Install the new crankshaft oil seal in the bearing cap groove. Form the seal and cut it off flush with the face of the cap. Use a sharp knife or razor blade and leave no ragged edges.

Repeat the procedure to form the upper half of the seal in the cylinder block groove. Install the bearing inserts. Lay the crankshaft in the block bearing halves, using care not to damage the thrust bearing (No. 3).

Install the bearing cap with seals, using the special guide fixture shown in Fig. 29, if available. Install the cap guide studs in the block. Place the bearing cap and fixture on the pilot studs and slide the cap over the studs and through the guide. Press the bearing cap carefully into place. Coat the surfaces lightly with grease to reduce friction during installation. *Be sure the cap-to-block seals do not shift while the cap is being installed.* The seal must be seated all the way down to prevent oil leakage at the parting edge of the block and cap.

Install the bearing cap bolts and torque them properly. The vertical cap-to-block seals should extend approximately $\frac{5}{64}$" above the block to insure a good seal against the oil pan gasket.

1952-53 L-Head V8

Oil sealing is controlled by a two-piece metal retainer having a groove which returns excess oil to the crankcase. These retainers can be replaced without removing the crankshaft by taking off the rear main bearing cap. The upper half of the retainer can be pushed around and taken out through the bottom.

Fig. 28 Forming rear bearing oil seal in cap. Overhead Valve engines

Fig. 29 Installing rear main bearing cap with special fixture. 1952-55 Overhead Valve V8-279 and V8-317. This tool is not necessary on other V8 engines

Fig. 30 Rear main bearing cap seals. Overhead Valve Sixes

1952-63 Six Cyl.

The rear main bearing cap contains the lower half of the crankcase journal oil seal and the cap itself is sealed to the block by two tapered vertical seals, Fig. 30.

With the crankshaft removed, take out the rear main bearing inserts and pry the seals from the block and cap. Clean the seal groove thoroughly.

Install a new journal oil seal in the bearing cap groove. Form the seal and cut it off flush with the face of the cap. Use a sharp knife and leave no ragged edges.

Repeat the procedure to form the upper half of the seal in the cylinder block groove. Install the bearing inserts. Lay the crankshaft in the block bearing halves, using care not to damage the thrust bearing (No. 3).

Install the bearing cap with seals, using special guide fixture shown in Fig. 31, if possible. Install the cap guide studs in the block. Place the bearing cap and fixture on the pilot studs and slide the cap over the studs and through the guide. Press the bearing cap carefully into place. Coat the surfaces lightly with grease to reduce friction during installation.

Be sure the cap-to-block seals do not shift while the cap is being installed. The seal must be seated all the way down to prevent oil leakage at the parting edge of the cap and block.

Fig. 31 Installing rear main bearing cap with aid of special guide fixture. 1952 Overhead Valve 6-215

Install the bearing cap bolts and torque them to 95-105 lbs. ft. The vertical cap-to-block seals should extend approximately $\frac{3}{64}$" above the block to insure a good seal against the oil pan gasket.

Check the cap-to-block seals by applying oil to the outside edges of the bearing cap. Apply compressed air to the corners of the cap inside of the block, and check the oil at the outside edge for bubbles. If any bubbling is appar-

ent, it will be necessary to remove the cap and reinstall it, making sure the cap-to-block seals seat all the way to the corner of the cap.

OIL PAN, REPLACE

1952-55 8-279 & 8-317

To remove the oil pan, disconnect the oil inlet tube at the pump. Remove the oil dipstick and tube. Unfasten and remove oil pan.

If it is necessary to remove the oil pump inlet tube and screen, remove the inlet tube retaining nut and pull the tube through the hole in the oil pan.

1954-55 8-239 & 8-256

To remove the pan, remove the engine front splash pans and disconnect the oil pump inlet tube at the pump. On Fordomatic equipped trucks, remove the converter housing dust cover. Crank the engine to bring No. 1 cylinder on top dead center. Then remove the oil pan.

If it is necessary to remove the oil pump inlet tube and screen from the pan, remove the retaining nut and pull the tube through the bore in the oil pan.

1956-57 V8s

1. To remove the pan, remove oil level dipstick and drain crankcase.
2. Remove engine front splash pans.
3. On Fordomatic equipped trucks, remove converter housing dust cover.
4. Disconnect oil inlet tube at pump and remove O-ring seal from pump end of tube.
5. On Tilt Cab trucks and on engines with Ram's Horn manifolds, crank engine to bring piston on TDC to remove oil pan.
6. On 302 and 332 engines, remove oil level indicator tube.
7. Unfasten and remove oil pan.

1954-57 Six Cyl.

To remove the oil pan, drain the crankcase and remove oil level dipstick. On 1957-58 models, remove engine left and right front splash aprons. Remove flywheel housing lower cover. Unfasten and remove the oil pan.

1958-63 Six Cyl.

To remove the pan, remove oil level dipstick and flywheel housing cover. Unfasten and remove oil pan after draining oil.

1958-63 V8-272, 292, 302, 332

1. To remove pan, drain oil and remove oil level dipstick.
2. On 302 and 332 engines, remove oil level dipstick tube.
3. On automatic transmission jobs, remove converter housing dust cover.
4. On Tilt Cab models, crank engine until No. 1 piston is up on T.D.C.
5. Disconnect oil pump inlet tube at oil pump. Remove "O" ring seal from pump end of tube.
6. Unfasten and remove oil pan.
7. Remove nut securing inlet tube to oil pan; then remove pump and screen from pan.

1958-63 V8-401, 477, 534

To remove pan, drain oil and remove oil level dipstick. Unfasten and remove oil pan.

1953 8-239

To remove the pan, remove the oil dipstick and tube. Remove starter motor and flywheel housing lower cover. Then unfasten and remove the oil pan.

1952-53 6-215

To remove the pan, pull the dipstick out of the tube, remove the retaining screws and drop the oil pan.

1952 8-239

To remove the oil pan, take off starter motor, clutch return spring and flywheel housing front cover. Remove road air breather duct. Remove steering gear arm and drop idler arm connecting rod until it hangs on spindle arms. Unscrew oil level indicator tube. Remove retaining screws and lower oil pan. *The two front screws can be reached through access holes provided in the frame front cross member. On some engines it will be necessary to disconnect the front engine supports and raise the front of the engine.*

1952-53 6-226 & 6-254

To remove the pan, take off splash pan and starter motor. Disconnect ventilator pipe bracket. Remove screws holding oil pan to engine rear plate. Unfasten oil pan from cylinder block and front cover plate and lower pan.

OIL PUMP REPAIRS

1954-55 8-239 & 8-256

To disassemble the pump, remove the cap screws retaining the cover to the pump body. Tap the cover gently with a soft hammer if stuck. *Do not tap on the end of the drive shaft.* Remove the gears from the body. Take out the relief valve parts. Pull the oil inlet pipe ferrule assembly from the large hole in the pump body.

Wash all parts and inspect the condition of each. The face of the pump cover should be checked for signs of wear or grooves that would cause an oil leak. Check the pressure relief valve plunger for wear. If a spring tester is available, check the tension of the relief valve spring which should be approximately 11 lbs. at 1.40". Check gears for signs of wear and pump body for cracks or excessive wear.

Replace any damaged parts and reassemble the pump.

1952-53 L-Head V8s

Before disassembling the pump, move the drive gear at the top of the unit from side to side. If the total movement is not in excess of .005", the pump need not be dismantled. If it is, however, it indicates worn bushings.

Fig. 32 Gear oil pump

To disassemble the pump, drive the pin from the drive gear and press the gear from the shaft. The bushings may then be pressed out of the housing and new ones installed.

When assembling the pump, press the gear onto the drive shaft so that there is .017" clearance between the bottom of the gear and the upper end of the pump body. Press the gear on at right angles to the old pin hole and drill a new hole in the shaft at that point. Use a $\frac{5}{32}$" drill and be guided by the hole in the gear hub when drilling the shaft. Install a new locking pin and peen the ends over so it won't work loose.

1952-53 L-Head Six

To disassemble, turn the pump upside down and turn the drive shaft until the outer rotor slips out of the housing. Drive out the pin securing the gear to the shaft, and press the gear off the shaft. The shaft and inner rotor may now be removed from the pump body.

To assemble, insert the inner rotor and shaft into the body. Line up the pin hole in the gear with the hole in the shaft and press the gear onto the shaft. New shafts are not drilled, and when installed as above, allow .004" drill clearance between the gear and body and drill the shaft. Then install the pin, peening over both ends so it won't work loose. Slide the outer rotor in position and install cover, using a new gasket.

1952-61 Six Cyl.

To disassemble the pump, Fig. 32, remove the upper drive shaft. Remove strainer and gasket. Take off the pump cover and remove the gears. Remove the lock wire and oil pressure relief valve parts.

Check the pump housing for cracks or excessive wear. The pump shaft should have a free running fit without excessive play in the bushings (.0005" to .0025"). Check the pump gear teeth for scratches or wear. Measure the clearance between

the outside diameter of the gears and pump housing, which should be no greater than .005″. Check the compression of the relief valve spring. It should be 9.82 lbs. (plus or minus 2 oz.) when the spring is compressed to 1.56″.

Replace any worn or defective parts and reassemble the pump. Do not use sealing compound on the pump cover gasket. Tighten the screws to 7-10 lbs. ft. torque. Install the pressure relief valve parts and tighten the plug to 40 lbs. ft. torque. Don't forget to lock the plug in place with a piece of wire.

1952-56 Overhead Valve V8 Gear Type Pump

To disassemble the pump, Fig. 33, remove the cover from the pump body. Remove the gears and pressure relief valve.

Check the pump housing for cracks or excessive wear. The pump shaft should have a free running fit without excessive play in the bushing (.0005″ to .0025″). Check the pump gear teeth for scratches or wear. Measure the clearance between the outside diameter of the gears and the pump housing—it should be no greater than .005″.

Check the compression of the relief valve spring. It should be 7.83 lbs. (plus or minus 2 oz.) when the spring is compressed 1.40″.

Replace worn or defective parts and reassemble the pump. Tighten cover plate screw to 8-10 lbs. ft. torque.

When installing the pump, insert the intermediate shaft in the block and rotate it slightly until it engages the distributor shaft. Note the position of the tang in the extension shaft and set the tang in the oil pump shaft so that it will engage with the slot. Place the pump housing in position on the block with a new gasket, install the three screws and tighten them to 15-20 lbs. ft. torque.

Do not use sealing compound on the gasket. Do not attempt to force the pump in position if it will not seat against the block. The tang on the pump driving shaft may be out of alignment with the tang in the intermediate shaft. Realign the tang if necessary.

1956-63 Overhead Valve V8 & 1962-63 Six Rotor Type Pump

When servicing the pump, the inner rotor and shaft, and the outer race are serviced as a kit. One part should not be replaced without replacing the other, Fig. 34.

When installing the pump, do not attempt to force it into position if it will not seat readily. The intermediate shaft hex may be misaligned with the distributor shaft. To align, rotate the intermediate shaft into a new position.

WATER PUMP, REPLACE

1954-55 Six-Cyl.

Two types of water pumps are used on these engines. One type has a fan and a sheet steel water pump pulley bolted to a pulley hub that is pressed on the pump shaft. The other type incorporates a cast iron pulley to drive the pump.

To remove the pump with the sheet steel pulley, remove the fan belt, fan and water pump pulley. Unfasten the pump from the block and lift it off.

To remove the pump having the cast iron pulley, remove the fan and generator belts. Then unfasten the pump from the block and lift it off.

1956-63 Six Cyl.

To remove pump, drain cooling system and disconnect lower hose and heater hose. Remove radiator, fan belt, fan and pump pulley. Unfasten and remove water pump from engine.

1958-63 V8-272, 292, 302, 332

To remove pump, drain cooling system and disconnect lower radiator hose, heater hose and water by-pass hose at water pump.

On low fan engines, remove fan belt, fan and pump pulley. Unfasten and remove pump from engine.

On high fan engines, remove fan belt, fan and bracket assembly, and generator belt. Unfasten and remove pump from engine.

Fig. 33 Gear type oil pump

Fig. 34 Rotor type oil pump

1958-63 V8-401, 477, 534

To remove water pump, drain cooling system and disconnect radiator lower hose, heater hose and water pump by-pass hose at pump. Remove fan belt or belts.

On B, F and T-Series trucks, remove fan and pulley and lower them into the bottom of the radiator shroud. Unfasten and remove pump from engine.

On C-series models, unfasten and remove pump from engine.

1952-53 6-215, 1952-53 8-279 & 8-317, All 1954-57 V8s

To remove the pump, disconnect the lower radiator hose, water by-pass and heater hose. Remove fan belt, fan and generator belt. Unfasten the pump from the block and lift it off.

1952-53 8-239

To remove the pump, take off fan belts. On 1952 models, place jack under engine, then remove two capscrews securing water pump to engine front support. On all models, remove capscrew located inside pump hose opening. Then remove other three screws and lift off pump.

1952-53 6-254

To remove the pump, take off the fan and pulley. Remove lower radiator hose and heater hose. Unfasten and remove pump from engine.

WATER PUMP REPAIRS

Figs. 35 to 41 illustrate the pumps used on the various engines. They are all of the sealed bearing type and repair kits are available when it becomes necessary to overhaul them.

RADIATOR, REPLACE

1958-63 B, F, T Series

1. Drain cooling system and disconnect upper and lower hoses.
2. On automatic transmission jobs, disconnect oil cooler lines at radiator.
3. If equipped with air compressor, remove compressor belt before removing fan assembly.

Fig. 35 Water pump. 1952-53 Overhead Valve Sixes

Fig. 36 Water pump. 1952-55 8-279 and 8-317 engines

Fig. 37 Water pump. 1956-57 Six

Fig. 38 Water pump. 1956-57 V8

Fig. 39 Water pump. V8-272, 292, 302, 332

Fig. 40 Water pump. V8-401, 477, 534

4. On F models with six-cylinder engine, unfasten and remove radiator.
5. On F and T models with 272 or 292 engine, loosen generator adjusting bracket bolts. Then remove fan, spacer, pulley and fan belt. Then unfasten and remove radiator.
6. On F and T models with 302 or 332 engine, remove fan belt, fan, pulley, and mounting bracket as an assembly. Then unfasten and remove radiator, shroud and hoses as an assembly.
7. On F and T models with a Super Duty engine, unfasten and lower fan into radiator shroud. Unfasten and tilt shroud to rear, then remove fan

Fig. 41 Water pump. 1958-63 Six-cylinder

through opening between shroud and radiator.
8. Unfasten and remove radiator and shroud.

1958-63 C Series

1. Drain cooling system and remove hose as necessary.
2. Disconnect transmission oil cooler lines at radiator (if equipped).
3. Remove air compressor drive belt (if equipped) before removing fan. On a truck with SD engine, unfasten and lower fan into shroud.
4. Disconnect linkage, cables, etc. attached to radiator.
5. Unfasten and remove radiator and shroud.

1958-63 P Series

1. Remove hood and drain cooling system.
2. Remove grille, headlamps, parking lamps, wind deflector and hood lower weatherstrip as an assembly.
3. Disconnect transmission oil cooler lines at radiator (if equipped).
4. On 6-cylinder trucks, remove fan and bracket as an assembly. Disconnect radiator hoses and remove radiator and shroud.
5. On trucks with 272 and 292 engines, remove fan, spacer, pulley and fan belt. Disconnect water hoses and remove radiator and shroud.

1956-57

To remove the radiator, drain cooling system and remove upper and lower hoses. On some models it is possible merely to remove the fan shroud attaching bolts, move the shroud back over the fan, then unfasten and remove the radiator.

On other truck models, remove the fan assembly, then remove the shroud and radiator as an assembly.

If equipped with an air compressor, remove the compressor belt, then remove the fan assembly. On Parcel Delivery models, it is necessary to remove the hood.

1953-55

If equipped with air compressor, remove compressor drive belt. On Parcel Delivery models, take off the hood.

On all models, take off fan, fan belt and all radiator hoses. Unfasten radiator from its mounting and lift out radiator and shroud.

1952

On Cab-Over-Engine models, take off the grille. On all models, remove fan blades and radiator retaining bolts. Lift out radiator and shroud.

THERMOSTATIC FAN

1956-58 8-302 & 332

A thermostatically-controlled fan, Fig. 42, is furnished as optional equipment on these engines. This fan free wheels when engine temperatures are low enough to make fan cooling unnecessary. Thus, engine efficiency is improved and the power needed to turn the fan is conserved.

The operation of the fan is controlled by a thermal unit mounted in the water outlet elbow. The operation of the thermal unit is similar to that of the engine thermostat. Expansion crystals, acting against a piston, open and close the contact points in response to engine temperature.

When the engine heats up to a specific temperature, the crystals expand and the points in the thermal unit close. This completes the circuit through the field coil mounted on the rotor and pulley assembly. The pulley assembly becomes magnetized and draws the armature into contact with the rotor facings so that the fan is driven, providing the additional cooling required.

When the engine is cold, or when the truck is operating at normal over-the-road speeds, the thermal unit contacts remain open. No current flows through the rotor and pulley assembly. The armature remains out of contact with the pulley rotor facings so that the fan free wheels.

Trouble Shooting

If the fan turns when the engine is cold, disconnect the field coil wire at the thermal unit. If the fan free wheels with the wire disconnected, the thermal unit should be replaced. If the fan continues to turn with the wire disconnected, remove the pulley and bracket assembly for repair.

If the fan will not turn when the engine is hot, place a jumper wire across the thermal unit terminals. If the fan now turns, replace the thermal unit. If the fan still does not turn, remove the pulley and bracket assembly for repairs.

Fig. 42 Thermostatic fan mechanism. 1956-58 302 and 332 engines

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

Carburetor & Governor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This

will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if the fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading on carburetors with automatic choke may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Automatic Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

CARBURETOR ADJUSTMENTS

Year	Engine	Carb. Type	Idle Screw Turns Open	Fast Idle Setting	Fuel Level	Float Level Primary	Float Level Secondary	Pump Setting	Dashpot Setting

FORD & HOLLEY NOTES

①—The fast idle screw is located in governor housing. With hot idle speed properly adjusted, and primary throttle plates closed, clearance between fast idle cam and head of fast idle screw should be as listed. If not correct, remove governor housing and insert a .060" diameter rod into hole in end of fast idle screw fitting to prevent it from turning. Then turn fast idle screw as required to obtain proper clearance.

②—With hot engine idle properly set and choke valve wide open, turn fast idle adjusting screw in until there is the clearance listed between screw and fast idle cam. To obtain clearance, turn screw in until it just touches fast idle cam, then back off ⅛ to ¼ turn.

③—Fuel level within bowl should be at lower edge of sight plug opening (plus or minus $\frac{1}{16}$"). With engine stopped, loosen lock screw on top of fuel bowl just enough to allow rotation of adjusting nut underneath. Turn adjusting nut as required to obtain proper level.

Fig. ④—Between floor of fuel bowl and bottom of float (fuel bowl inverted).

⑤—Pump stroke controlled by two holes in pump cam with top hole for short stroke (summer), lower hole for winter operation. To adjust pump lever screw, with primary throttle valves wide open there should be .015" clearance between pump lever adjusting screw head and pump arm with pump arm fully depressed (manually). Turn screw in to increase clearance and vice-versa.

Fig. ⑥—Below power valve mounting surface (plus or minus $\frac{1}{32}$").

⑦—From roof of float chamber to lowest point of float (carb. inverted).

Fig. ⑧—Dashpot setting.

⑨—Seasonal setting. Inner hole for long stroke, outer for short stroke.

⑩—Below centerline of main discharge nozzles.

⑪—Lower edge of sight plug opening.

⑫—Below surface of fuel bowl.

Fig. ⑬—From 1.437" to 1.5" from air horn gasket surface to bottom of float.

⑭—Three holes are provided in throttle lever for seasonal settings. Shortest stroke for hot weather, center hole for average conditions and longest stroke for winter.

⑮—Primary ½", secondary ⅝". Measure from below centerline of main discharge nozzles.

⑯—Measured from flange surface of main body with engine idling.

Fig. ⑰—From flange surface to top of float.

CARBURETOR GOVERNOR

Vacuum Type Governor, Fig. 1

The vacuum type governor consists of two units, the governor rotor and housing (on which the distributor is mounted), and the diaphragm control assembly, mounted on the side of the carburetor throttle body. These units are connected by two vacuum lines.

A driveaway throttle stop is installed in the diaphragm control housing of new vehicles. This stop must be removed before putting the truck in service because it severely limits the amount of throttle opening attainable.

To remove the throttle stop, take off the cover plate and remove the screw retaining the throttle stop and remove the stop.

Vacuum Governor, Adjust

Connect a tachometer to the engine. Run the engine until normal operating temperature has been reached. Then run then engine at wide open throttle and note the engine speed registered.

Stop the engine and remove the adjusting hole plug from the controlling unit housing. With ignition switch off, crank the engine until the governor valve adjusting screw is aligned with the adjustment hole. Turn the adjusting screw clockwise to increase speed and counter-clockwise to decrease speed. One full turn of the adjusting screw will change top speed about 150 rpm. Replace the plug.

Start the engine and gradually increase the throttle opening, observing the tachometer, until the no-load cut-off speed is reached. If the cut-off is not

Fig. 2 Velocity type governor

Fig. 1 Vacuum type governor disassembled

within the specified range, stop the engine and make the necessary correction at the governor adjusting screw. Repeat the test until the correct cut-off speed is obtained.

Before sealing the governor, make sure the air bleed pipe union nuts and the adjusting hole plug are tight. Air entering the diaphragm from any source other than the rotor orifice will cause faulty governor control.

Velocity Type Governor, Fig. 2

The velocity type governor, Fig. 2 has a single unit for controlling engine speed. It is mounted between the carburetor and intake manifold. No provision for repair of this type governor is provided; therefore, it should be replaced when it becomes defective.

The governor is adjusted by turning an adjusting cap on the spring housing. If the engine rpm must be increased, turn the cap counterclockwise. If it has to be decreased, turn the cap clockwise. When final adjustment is complete, seal the cap to the mounting studs with a governor seal.

Clutch Section

HYDRAULIC CLUTCH RELEASE, 1957-63

On these models, the clutch is released by a hydraulic system, Figs. 1 and 2. When the clutch pedal is depressed, fluid is forced from the master cylinder into a slave cylinder. The slave cylinder push rod moves the clutch release lever which in turn pivots on a trunnion in the flywheel housing, and forces the release bearing against the pressure plate release fingers.

When the clutch pedal is released, the master cylinder return spring and the release lever retracting spring force the fluid from the slave cylinder back to the master cylinder.

The fluid used in this system is the same as that used in the brake system. A bleeder fitting is installed on the slave cylinder and procedures for bleeding are the same as those for brakes. The master cylinder fluid level should be maintained at ½" below the top of the master cylinder reservoir.

Fig. 1 Clutch and linkage. Typical F Series

CLUTCH PEDAL, ADJUST

Mechanical Release, 1961-63

1. Adjust clutch pedal stop to permit total pedal travel of $8\frac{1}{16}$" to $8\frac{5}{16}$".
2. Adjust clutch pedal free travel to 1⅜" to 1½" by backing off jam nut and adjusting spherical nut on release push rod. There should be ¼" clearance between spherical nut and release lever. Make this adjustment with retracting spring in place. Tighten jam nut.

Hydraulic Release, 1961-63

Before making any adjustments, be sure that the system is free of air and that the master cylinder fluid is at the specified level.

F and T Series

1. Adjust pedal stop to permit total pedal travel of $8\frac{1}{16}$" to $8\frac{3}{16}$".
2. Set clutch pedal initial free travel to $\frac{3}{16}$" to ⅜" by adjusting the eccentric bolt. This measurement is taken at the centerline of the pedal pad.
3. If necessary, readjust pedal stop to maintain initial specified free travel.
4. With retracting spring disconnected, push slave cylinder push rod toward front of truck as far as possible. Pull release lever back until release bearing touches pressure plate release fingers.
5. Adjust clearance between slave cylinder push rod spherical nut and release lever to ¼" ($\frac{3}{16}$" on 850 to 1100 Series) for proper free travel. Tighten jam nut. *As a result of this adjustment, there should be a final free travel of at least 2". Do not change proper free travel adjustments to bring about desired total travel.*

C Series

1. Adjust eccentric bolt and pedal stop to give $\frac{5}{32}$" to ¼" of initial free travel before master cylinder push rod contacts piston. This measurement is taken at centerline of pedal pad.
2. Disconnect release lever retracting spring. Push slave cylinder push rod the full distance of its travel toward front of truck. Pull release lever toward rear of truck until release bearing touches release fingers.
3. Adjust clearance between slave cylinder push rod spherical nut and release lever to $\frac{3}{16}$" (¼" on 850 to 1100 Series) to obtain final pedal travel. As a result of this adjustment, there should be a final free travel of approximately 1½" (2" on 850 to 1100 Series). Tighten jam nut.

H and HT Series

1. Adjust clutch pedal height to 10⅜" by moving bumper and its bracket.
2. By means of eccentric bolt, adjust initial free pedal travel ⅛" to ¼".
3. Disconnect release lever retracting spring. Push slave cylinder push rod the full distance of its travel for-

Fig. 2 Clutch and linkage. Typical C Series

Fig. 3 Slave cylinder push rod adjustment

Fig. 4 Hydraulic clutch release slave cylinder and release lever. Dimension indicated to be not less than 1/4"

Fig. 5 Clutch and linkage. 1953-56 (typical)

ward, and move release lever to the rear until release bearing touches release fingers.

4. Adjust clearance between slave cylinder push rod spherical nut and release lever to $\frac{3}{16}$" to obtain final free travel. As a result of this adjustment, there should be final free travel of approximately 1½". Tighten jam nut.

P Series

1. Adjust clutch master cylinder push rod extension to give $\frac{1}{16}$" to ¼" initial free travel. This adjustment should be checked with clutch pedal retracting spring attached.
2. Disconnect release lever retracting spring. Adjust clearance between slave cylinder push rod spherical nut and clutch release lever to ¼". As a result of this adjustment, there should be a final free travel of at least 2".

1959-60

1. Adjust clutch pedal total travel by locating clutch pedal bumper so that clutch pedal pad in fully released position is even with brake pedal pad.
2. Disconnect clutch release lever retracting spring. *Do not put pressure on clutch pedal while spring is disconnected.*
3. Bottom slave cylinder push rod and piston by pushing slave cylinder push rod toward front of vehicle as far as it will go.
4. Pull release lever toward rear of truck until release bearing touches pressure plate release fingers.
5. Adjust clearance between slave cylinder push rod adjusting nut and clutch release lever to no less than ¼". Tighten lock nut.
6. Adjust clutch master cylinder push rod eccentric bolt to obtain $\frac{3}{16}$" to ⅜" (¼" on C Series) free travel measured at the centerline of the pedal pad before push rod touches master cylinder.
7. Check free travel at clutch pedal.

The adjusted clearance at slave cylinder push rod and pedal free travel at master cylinder push rod should result in final free travel of at least 2" ($1\frac{13}{16}$" on C Series). *An F, C or T Series truck with a Super Duty engine should have 1⅝" clearance.*

1957-58

There are only two adjustments which can be made on the clutch. The clutch pedal total travel and the clutch pedal free travel.

The pedal total travel should be adjusted so that the clutch pedal pad at the fully-released position is parallel with the brake pedal pad.

The clutch pedal free travel should be adjusted to not less than 1¾" and not more than 2". It can be adjusted as follows:

1. Adjust clutch pedal total travel so that pedal pad in the fully-released position is even with brake pedal pad.
2. Disconnect the clutch release lever retracting spring.
3. Bottom the slave cylinder push rod and piston by pushing the slave cylinder push rod toward the front of the truck as far as it will go, Fig. 3.
4. Pull the release lever toward the rear of the truck until the release bearing touches the pressure plate release fingers.
5. Adjust the clearance between the slave cylinder push rod adjusting nut and the clutch release lever to ¼", Fig. 4.
6. Adjust the clutch master cylinder push rod eccentric bolt to obtain ¼" free travel at the pedal pad before the push rod touches the master cylinder piston. On Parcel Delivery trucks, adjust the master cylinder extension rod to obtain ¼" free travel at the pedal pad.
7. Check the free travel at the clutch pedal. The above adjustments should result in a clutch pedal free travel of 1¾ to 2".

1952-56

The only clutch adjustment required is the clutch pedal free travel. To check the free travel, depress the clutch pedal by hand, then measure the distance the clutch pedal travels before the clutch begins to engage.

The free pedal travel for all trucks is 1⅛ to 1⅜". If the free travel is not within these limits, adjust as follows:

On 1952 models, remove the clevis pin connecting the pedal to the release arm rod and rotate the clevis until the proper free pedal travel is obtained. Install the clevis pin.

On 1953-56 models, loosen the lock nut on the forward end of the clutch release lever rod and turn the adjusting nut on the rod until the proper pedal free travel is obtained. Hold the adjusting nut and tighten the lock nut securely, Fig. 5.

CLUTCH REPLACE

1. On 1952 models, disconnect clutch release equalizer shaft from clutch release shaft. Remove transmission with clutch housing where separate housing is used. Unhook clutch release bearing spring and remove the clutch release bearing and hub from the transmission main drive gear bearing retainer. Remove the two-piece flywheel housing or one-piece housing, depending on the type being serviced.
2. On 1953-61 models, disconnect clutch pedal retracting spring from clutch release lever. On 1957-63 models, remove the two bolts which attach the slave cylinder to the flywheel housing and remove the slave cylinder push rod from the release lever. Remove release lever rod. Remove transmission from clutch housing. Remove release bearing and hub from release lever, Figs. 1, 2, 4.
3. On all models, mark the clutch assembly and flywheel so the parts may be installed in the same relative position.
4. Loosen the clutch-to-flywheel attaching bolts a little at a time until the tension on the clutch springs is relieved. Then unscrew the bolts completely and remove the clutch assembly and driven disc.

Installation

1. Coat pilot bearing bore in flywheel with a small amount of wheel bearing grease. *Avoid using too much grease as it may be thrown on the clutch disc when the clutch revolves.*
2. Install pilot bearing in flywheel. On 12" clutch, install the bearing with its shielded side toward the rear.
3. Install clutch pilot tool in clutch disc and position disc on flywheel so that the pilot tool enters the pilot bearing.
4. Position pressure plate and cover assembly on flywheel and install the retaining cap screws. Tighten the cap screws to a torque of 17-20 lb. ft. If the original clutch is being installed, be sure to align the marks made prior to removal.
5. On 1952 models, remove the pilot tool and attach the flywheel housing to the engine and torque the bolts to 37-42 lb. ft. Place the clutch release bearing and hub on the transmission main drive gear bearing retainer, then install the release bearing retracting spring. Install the transmission. Connect the clutch equalizer shaft to the release shaft and adjust the clutch pedal free play.
6. On 1953-60 models, position the release bearing and hub on the release lever. Install the transmission. Position release bearing and hub on the release lever. On 1957-60 models, install the slave cylinder and adjust the push rod. Position the release lever rod in the equalizer bar and in the release lever. Install adjusting nut and lock nut on release rod. Connect the clutch pedal retracting spring to the release lever and check the clutch pedal free travel.

Manual Shift Transmission Section

For Clark, Fuller, New Process, Spicer and Warner transmissions used on Ford trucks, see the "name" chapter for service procedures and lubricant capacities

3 SPEED UNITS

Remove & Replace, 1952

1. Remove seat cushion and floor plate.
2. Support rear of engine.
3. Disconnect drive shaft.
4. If equipped with remote control gearshift mechanism, disconnect linkage at transmission.
5. Disconnect clutch equalizer shaft.
6. Disconnect speedometer cable.
7. Disconnect transmission at engine rear support and at flywheel housing.
8. Pull transmission to rear and lift out through floor opening.
9. Reverse foregoing to install.

Remove & Replace, 1953-57

1. Remove floor mat and floor plate.
2. Loosen two nuts that secure top of transmission to clutch housing studs.
3. Raise truck and drain lubricant from transmission.
4. Disconnect drive shaft.
5. If truck is equipped with band-type parking brake, disconnect cable at brake and at gear shift housing.
6. Disconnect gear shift linkage at transmission, then disconnect clutch pedal retracting spring from clutch release lever.
7. Remove capscrews which attach clutch release equalizer bar anchor bracket to transmission.
8. Disconnect speedometer cable.
9. Remove dust cover from bottom of clutch housing.
10. Place jack under transmission.
11. Unfasten transmission from clutch housing, pull transmission to the rear end and lower it to the floor.
12. Reverse the foregoing to install.

Remove & Replace, 1958-62

1. Place jack under transmission and disconnect speedometer cable.

Fig. 1 Ford light duty three-speed transmission. 1953-62

2. Disconnect gearshift linkage at transmission.
3. If equipped with band-type parking brake band, disconnect brake cable clevis at cam and remove cable conduit clamp.
4. Disconnect drive shaft.
5. Remove transmission attaching bolts and attach guide studs.
6. Move transmission to the rear until clutch gear shaft clears clutch housing and lower transmission.

Ford Trans. Disassemble

1. Referring to Figs. 1 and 2, remove gear shift housing.
2. With a punch, drive out retainer from countershaft and reverse idler shaft.
3. Unfasten extension housing and turn it counterclockwise to permit removal of countershaft.
4. Drive countershaft toward rear of case until shaft just clears hole in front of case. Push countershaft out of rear of case, allowing cluster gear assembly to lie in bottom of case.
5. Extension housing and mainshaft assembly can now be removed from the case. Some of the mainshaft pilot bearing rollers may fall to the bottom of the case.
6. To disassemble the mainshaft, remove the snap ring from the front of the shaft and strip the shaft of its parts. The synchronizer may be disassembled by sliding the clutch sleeve off the hub and removing the three inserts and insert rings.
7. Remove clutch gear through front of case.
8. Drive out reverse idler shaft and lift out gear.
9. Remove countershaft cluster gear assembly.

Fig. 2 Gearshift housing for Fig. 1 transmission

Assembly Notes

Reverse the disassembly procedure to assemble the transmission, referring to Fig. 1. It is not necessary to disassemble the gearshaft housing to determine the condition of the parts. Check the condition of the shift levers and forks. If there is any binding or possibility of shifting into two gears at once when the lever is operated, disassemble and assemble the housing, referring to Fig. 2.

If the clutch shaft bearing does not have a built-in shield, a baffle is used at the rear of the bearing. The baffle must be installed with the dished side away from the bearing so that the baffle does not rub the outer race of the bearing.

When assembling the cluster gear, first center the bearing spacer in the gear. Then install a flat washer, 25 rollers and a second flat washer at each end of the cluster gear. Place the thrust washers at each end of the gear with the flat side next to the gear. To obtain the specified end play of .004″ to .018″, change the thrust washers as required.

Reverse idler gear is installed with the chamfered teeth ends toward the front.

When installing the clutch shaft bearing retainer, be sure to align the oil drain in the retainer with the hole in the case.

When installing the mainshaft and bearing into the extension housing, install the thickest snap ring that will fit. Snap rings are available in four thicknesses, ranging from .086″ to .097″. When mainshaft and extension housing is installed in case, shaft end play must not exceed .003″.

Fig. 3 Three speed transmission gear train. 1963

3 SPEED TRANS., 1963

1. To disassemble the transmission, Fig. 3, remove bottom drain plug and drain lubricant.
2. Remove parts shown in Fig. 4.
3. Remove filler plug from right side of case and drive out the countershaft retainer, Fig. 5. Lower countershaft assembly to bottom of case.
4. Lift input shaft gear and shaft from front of case, being careful not to drop needle bearings from bore of input shaft.
5. Slide speedometer drive gear from mainshaft and remove the drive gear lock ball from shaft.
6. Use a suitable puller to remove mainshaft rear bearing.
7. Place both shift levers in neutral position.
8. Remove plug that retains detent plunger and spring in case and remove these parts, Fig. 6.
9. Remove shift fork components.
10. Lift mainshaft assembly out through top of case.
11. Working through front bearing opening, drive reverse idler gear shaft out through rear of case with a drift. Then lift reverse idler gear and two thrust washers from case.
12. Lift countershaft and thrust washers from case, using a dummy shaft to hold needle bearings in place.
13. Remove shift levers and shafts, Fig. 7.
14. Remove snap ring from front end of mainshaft and slide synchronizer and second speed gear off shaft.
15. Remove snap ring and thrust washer from mainshaft and slide first speed gear and blocking ring off shaft.
16. Remove the next snap ring and slide reverse gear and sleeve from shaft.
17. Remove dummy shaft, needle bearings and two retainer washers from countershaft gear.
18. Disassemble synchronizers.
19. Assemble the transmission in the reverse order of disassembly, referring to Figs. 4 to 12. Countergear and reverse idler gear end play should be .004 to .018″. Replace thrust washers as required to obtain this end play.

Fig. 11 Rear synchronizer disassembled

Fig. 9 Mainshaft disassembled

Fig. 12 Countershaft disassembled

Fig. 8 Input shaft disassembled

TILT CAB SHIFT LINKAGE

1957 Adjustment

1. Referring to Fig. 13, shift transmission into neutral.
2. Remove split pin that retains rear universal joint to the finger socket shaft in the rear cross shaft housing.
3. Loosen lock nut at front of front control rod universal joint.
4. Hold gearshift front cross shaft so that the cross shaft arm and control rod crank arm are in a vertical position.
5. Rotate rear control rod front universal joint on its thread until the pin hole in the rear universal joint lines

up with the hole in the finger socket shaft. Install the split pin. Tighten lock nut at rear control rod front universal joint.
6. Check adjustment by shifting through all gears.

1958-63 Adjustment

1. Shift transmission into neutral and tilt the cab.
2. Loosen both turnbuckle bolts, Fig. 14.
3. Rotate turnbuckle until front cross shaft arm is vertical.
4. Using a drift or a screwdriver, turn rear U-joint counterclockwise (viewed from rear) until rear cross shaft finger bottoms the plunger (except on Spicer units) in the transmission shift housing. On a Spicer transmission, rotate U-joint until the finger bottoms firmly in the gate.
5. Holding the finger in position, rotate the shift control rear rod until there is the specified distance (see below) between inner surface of cross shaft lever and right-hand end of cross shaft tube.
6. Tighten turnbuckle bolts.
7. Lower cab and check operation of gearshift lever in all positions. If lever hits either the instrument panel or the seat, readjust turnbuckle repeating Steps 4 through 7, except that dimensions in table below may be reduced. *In any case, the dimension should not be more than ⅛".*

Fig. 13 Tilt cab shift linkage. 1957

Fig. 14 Tilt cab shift linkage. 1958-63

Automatic Transmission Section

For Allison Transmatic, Fordomatic and Cruiseomatic transmissions, see the "name" chapters for service procedures

FORDOMATIC & CRUISEOMATIC

Engine Idling Speed

1. Apply parking brake and place selector lever in N.
2. Run engine at normal idle speed. If transmission fluid is cold, run engine at fast idle speed until fluid warms up. When fluid is warm, slow engine down to normal idle speed.
3. Connect a tachometer to engine.
4. Adjust engine idle speed to 450 rpm with selector lever at Dr, D2 or D1.
5. It may be necessary to readjust the idle speed at N position to obtain the correct speed at the Drive positions. *If the anti-stall dashpot holds the throttle open and prevents the idle speed from being correctly adjusted, adjust the dashpot clearance before setting idle speed.*

Anti-Stall Dashpot

After the engine idle speed has been correctly adjusted, stop the engine and adjust the anti-stall dashpot clearance.

1. Loosen dashpot lock nut.
2. With throttle in the hot idle position, bottom the dashpot plunger and measure the clearance between the bottomed plunger and the throttle shaft lever. Clearance should be .045" to .064".
3. To adjust clearance, turn the dashpot or dashpot adjusting nut and tighten the lock nut after the proper clearance is obtained.

Manual Linkage

1. With engine stopped, disconnect upper end of manual shift rod and

clevis from selector lever.
2. Position selector lever so that pointer is down against the steering column stop in the Dr position.
3. Shift manual lever on transmission to the Dr detent (2nd from bottom).
4. Rotate clevis on manual shift rod until clevis pin can easily be inserted in lever insulator. Then lengthen rod by turning the clevis two full turns.
5. Lock clevis in place and connect rod and clevis to lever.
6. Check pointer alignment for all positions of selector lever.

Starter Neutral Switch

Check the starter circuit in all selector lever positions. The circuit must be open in all positions except N and P.

To adjust the switch, loosen the attaching screws and position the switch so that the starter circuit is closed only when the selector lever is at N and P.

Throttle Linkage, 1953-54

8-Cylinder—With the engine idling speed and anti-stall dashpot properly adjusted, place the linkage adjustment tool, Fig. 1, on the end of the carburetor-to-Z-bar rod so the tool rests on a clean, finished surface of the cylinder block.

Loosen the lock nut on the carburetor-to-Z-bar rod and turn the barrel of the rod until the idle adjustment screw just touches the stop when the rod is held at the bottom of the tool slot (2.04" from surface of block to centerline of rod). Tighten the lock nut and remove the tool.

Remove the clevis pin from the upper end of the Z-bar-to-transmission rod and pull upward gently but firmly on the rod to hold the transmission lever against its internal stop.

Adjust the clevis until the clevis pin will freely enter the holes in the clevis and Z-bar. Lengthen the rod by turning the clevis 2½ turns counterclockwise.

Check the operation of the transmission. And if clutch or band slippage occurs at part throttle increase the rod adjustment to 3 full turns but not more than 3½.

Measure the distance from the floor pan (not floor mat) to the pivot point under the accelerator pedal, Fig. 2. If the distance is not correct as shown, adjust the accelerator cross shaft-to-carburetor rod until the correct pedal height is obtained.

If the accelerator pedal stop bolt prevents kickdown action, loosen the lock nut and adjust the stop bolt height to obtain the kickdown.

6-Cylinder—With the engine idling speed and anti-stall dashpot properly adjusted, remove the pin from the clevis of the transmission-to-Z-bar rod and turn the clevis until the holes in the clevis and mating lever are aligned. Turn the clevis 2½ turns counterclockwise and install the clevis pin.

If clutch or band slippage occurs at part throttle after adjustment has been made, increase the rod adjustment to 3 turns but do not exceed 3½.

If the distance between the floor pan to the pivot point under the accelerator is not as shown in Fig. 2, adjust the accelerator cross shaft-to-carburetor rod as required to obtain the correct pedal height.

Fig. 1 Throttle linkage adjustment 1953-54 eight-cyl.

Fig. 2 Pedal height adjustment. 1953-54

Fig. 3 Throttle linkage. 1955 six-cyl.

Throttle Linkage, 1955

6-Cylinder—Remove the clevis pin from the upper end of the throttle control rod, Fig. 3. Pull upward on the rod to hold the transmission lever against its internal stop.

Rotate the throttle rod clevis until the clevis pin can freely enter the holes in the clevis and accelerator shaft. Then lengthen the rod by rotating the clevis 3 turns and install the clevis.

Adjust the accelerator pedal height so that the pedal just touches the detent stem when the carburetor lever hits its wide-open stop, Fig. 4.

After the adjustment is completed, road test the truck and if band or clutch slippage is evident, increase the length of the rod to 3½ turns but do not exceed 4 turns.

Fig. 4 Accelerator pedal detent. 1955

8-Cylinder—Position the throttle linkage adjustment tool on the clean surface of the accelerator assembly mounting bracket. The lower pin of the tool should freely enter the hole in the accelerator lever, Fig. 5. If the pin does not enter the hole in the lever, rotate the carburetor connecting link barrel until it enters with the carburetor idle adjustment screw against its stop. Tighten the lock nut.

Remove the clevis pin from the upper end of the throttle control rod. Pull upward on the rod to hold the transmission lever against its internal stop.

Rotate the throttle control rod clevis until the clevis pin freely enters the holes in the clevis and accelerator lever. Then lengthen the rod 3 turns.

After the adjustment, road test the truck and if band or clutch slippage is evident, increase the throttle rod length to 3½ turns but do not exceed 4 turns.

Check the alignment of the accelerator cross shaft-to-accelerator lever connecting link. The link must be parallel with the centerline of the engine. If not, turn the adjustment screw until the correct alignment is obtained.

Adjust the accelerator pedal height so the pedal just touches the detent stem when the carburetor lever hits its wide-open stop, Fig. 4.

Throttle Linkage, 1956-57

6 Cylinder—To adjust, remove the clevis pin from the upper end of the throttle control rod, Figs. 6 and 7. Pull upward firmly but gently on the throttle

Fig. 5 Throttle linkage. 1955 eight-cyl.

Fig. 6 Throttle linkage. 1956-57 Six except Parcel Delivery

Fig. 7 Throttle linkage. 1956-57 Six Parcel Delivery

Fig. 8 Throttle linkage. 1956-57 V8s

control rod to hold the transmission lever against its internal stop.

Rotate the throttle rod clevis until the clevis pin enters the holes in the clevis and accelerator assembly shaft. Lengthen the throttle control rod by rotating the clevis 2½ turns, and assemble the throttle rod to the accelerator shaft.

Adjust the accelerator connecting link to obtain a pedal height of 2⅝″ on 1956 models and 2¾″ on 1957 models. The pedal just touches the detent stem when the carburetor lever hits its wide-open stop.

Check the throttle linkage and relieve any binding conditions. Road test the truck. If band or clutch slippage is evident, increase the rod length to 3 turns of the clevis, but do not exceed 3½ turns.

8 Cylinder—Disconnect throttle rod from accelerator assembly, Fig. 8, and insert a ¼″ drill rod through the holes at point "A". Adjust the length of the carburetor connecting link to close the carburetor against its stop. Adjust the accelerator assembly connecting link to obtain a pedal height of 2⅝″ on 1956 models and 2¾″ on 1957. The pedal should just touch the detent when the carburetor lever hits its wide-open stop. Remove the drill rod and check the alignment at "A". The pin must re-enter freely.

Remove the drill rod and adjust the throttle control rod. Pull upward gently but firmly on the rod to hold the transmission lever against its internal stop.

Rotate the clevis until it freely fits the pin on the accelerator lever. Lengthen the throttle control rod by rotating the clevis 2½ turns. Assemble the parts and tighten the lock nut.

Road test the truck and if band or clutch slippage is evident, increase the length of the throttle control rod to 3 turns, but do not exceed 3½ turns.

Throttle Linkage, 1958-63 Six-Cyl.

1. With engine stopped, loosen clevis lock nut on upper end of throttle rod.
2. Remove clevis and pull throttle rod upward to hold throttle lever against the main control stop, Fig. 9.
3. Turn the throttle rod clevis until clevis pin enters hole in lever. Lengthen throttle rod 2½ turns to obtain an approximate setting.
4. Connect throttle rod to accelerator shaft and temporarily secure it with cotter pin.
5. Adjust accelerator pedal height by turning threaded trunnion on accelerator connecting link until the point where linkage connects to pedal is 2¾″ from floor mat.

Throttle Linkage, 1958-63 V8

1. With engine stopped, disconnect throttle rod from accelerator, Figs. 10 or 11.
2. Insert ¼″ drill rod through gauging holes shown in Fig. 10.
3. Adjust length of carburetor connecting link so that carburetor throttle is at idle position.
4. Adjust accelerator connecting link to obtain a pedal height of 2¾″.
5. Remove gauge pin and check alignment of holes. Pin must enter freely.

Fig. 9 Throttle linkage. 1958-63 Six-cyl. (except P Series)

Fig. 10 Throttle linkage. 1958-63 V8 (except P series)

Fig. 11 Throttle linkage. 1958-63 V8 P Series trucks

6. Remove gauge pin and adjust throttle control rod. Pull upward gently but firmly on the rod to hold transmission lever against its internal stop.
7. Rotate clevis until it freely fits pin on accelerator lever. Lengthen throttle rod by rotating clevis 3 turns counterclockwise.
8. Connect throttle rod to accelerator lever.

Transmission & Converter, Replace 1953-58

1. Drain radiator, fold back front of floor mat and remove covers from converter housing bolt access holes.
2. Pull off cooler hoses.

3. Remove two upper converter housing-to-engine bolts.
4. Raise vehicle with hoist.
5. Disconnect oil filler tube at oil pan and drain transmission.
6. Remove converter housing front plates (8-cyl.) or access plate (6-cyl.).
7. Drain converter now or wait until unit is removed.
8. Remove drive shaft at rear axle.
9. On F-250, F-350 and P-350 models, remove 4 bolts attaching drive shaft coupling yoke at parking brake.
10. Remove 6 flywheel - to - converter drive plate bolts.
11. Position drive plate horizontally and wedge the converter from sliding out of the housing when the transmission is removed.
12. Disconnect starter cable at starter and transmission-to-frame ground cable at transmission.
13. Remove starter and oil cooler.
14. Remove exhaust duct shield.
15. Disconnect manual and throttle linkage at transmission, and speedometer cable.
16. Support transmission with jack and remove converter housing to cross member bolts.
17. Remove two lower converter housing-to-engine bolts.
18. Tilt rear of transmission and converter upward slightly and move the assembly toward the rear to gain access to the 6 crankshaft flange-to-flywheel bolts.
19. Remove the flywheel to provide clearance and lower the transmission and converter assembly.
20. To install, reverse the foregoing procedure.

Transmission Only, Replace

1953-58

1. Raise vehicle on hoist.
2. Disconnect fluid filler tube at oil pan and drain fluid.
3. Remove drive shaft.
4. Unfasten cooler and move to one side.
5. Remove exhaust duct shield.
6. Disconnect manual and throttle linkage and speedometer cable from transmission.
7. Support transmission with jack and unfasten transmission from converter.
8. Remove oil cooler front support bracket.
9. Tilt rear of transmission slightly upward and move to the rear until clear of turbine shaft. Then lower assembly and remove from vehicle.
10. Reverse the foregoing to install.

TRANSMATIC DRIVE

1958-63

For a detailed description on the operation and servicing of this transmission see the *Allison Chapter* elsewhere in this manual. The following material deals with linkage adjustments and removal of the unit from the truck.

Fig. 12. Transmatic range selector linkage. Conventional cab models

Range Selector Linkage, Adjust

1. Place the selector lever at R.
2. Check the distance that the control cable adjusting threads extend above the sleeve assembled to the range selector arm, Figs. 12 and 13.
3. At the transmission, disconnect the range selector cable from the transmission control lever.
4. Shift the transmission control lever to R (all the way forward and upward).
5. Push the control cable up until the selector lever hits the R stop. Adjust the threaded sleeve so that the sleeve pin fits the hole in the control lever.
6. Assemble the sleeve to the lever.
7. From the driver's seat, feel for full engagement at each detent position before the lever hits its stop.

Fig. 13 Transmatic range selector linkage. Tilt cab models

Neutral Safety Switch, Adjust

Check the starter circuit at all selector lever positions. The circuit must be open at all positions except Neutral. To adjust, loosen the switch attaching screws. Position the switch so that the starter circuit is closed when the selector lever is in Neutral.

Throttle Linkage, Adjust

Conventional Cab Models—

1. With engine at normal operating temperature, check engine idle speed which should be 475-500 rpm with selector lever in Neutral.
2. Stop engine. Then disconnect throttle control rod, Fig. 14, at shaft and bracket assembly.
3. Lock linkage in full throttle position by inserting a ¼″ drill or rod into the shaft and bracket.
4. With gauge in place, adjust carburetor connecting link so that carburetor throttle lever is against its wide open stop.
5. With gauge still in place, pull throttle control rod upward until the transmission throttle lever is against its stop inside the transmission. *The throttle control rod should be assembled to the outer hole of the transmission throttle lever.*
6. While holding the throttle control rod firmly against its stop, adjust the throttle control rod clevis so that it just fits the pin on the shaft and bracket assembly.
7. Lengthen the throttle control rod by rotating the clevis counterclockwise 10 turns (272 engine) or 9 turns (302 and 322 engines). Then assemble the clevis to the shaft pin.
8. Remove the gauge rod or drill. With linkage and carburetor in the hot idle position, move screw up or down in bracket slot to provide .020″ clearance between bell crank and screw head. Tighten screw.
9. Adjust accelerator pedal connecting link to obtain proper pedal height.
10. Check linkage for free movement in all positions.

Tilt Cab Models—

Adjustment procedures for these models are the same as those for conventional models except for pedal heights, Fig. 15.

Hydraulic Retarder Linkage, Adjust

Conventional Cab Models—

1. Check hydraulic retarder pedal stop bolt height against dimension shown in Fig. 16. Adjust as required.
2. Disconnect hydraulic retarder control rod at transmission end. Pull retarder lever toward the rear of the transmission until retarder valve is heard and felt to bottom in the retarder casting.
3. Pull the control rod down until the pedal contacts its stop bolt.
4. Adjust control rod threaded sleeve until pin just fits in lever hole.
5. Lengthen control rod by rotating sleeve counterclockwise to provide ⅛″ clearance between pedal and stop at full retarder application.
6. Assemble control rod to lever and tighten lock nut.
7. Check adjustment by depressing pedal against stop bolt. Just before pedal hits stop bolt, retarder valve should be felt to bottom in its body. Check for full release and readjust if necessary.

Tilt Cab Models—

1. Adjust pedal retarder stop bolt height as shown in Fig. 17.
2. Disconnect retarder control cable at transmission.
3. Pull retarder lever toward rear of transmission until retarder valve is heard and felt to bottom in its body.
4. Pull retarder cable toward transmission until pedal is against its stop bolt.
5. With retarder valve bottomed (all the way to rear) and retarder pedal against its stop, adjust cable adjusting sleeve until sleeve pin just fits hole in lever.
6. Lengthen cable by turning sleeve counterclockwise to provide about ⅛″ clearance between pedal and stop at full retarder application.
7. Assemble cable to lever.

Fig. 14 Transmatic throttle linkage. Conventional cab models with 302 and 332 engines

Fig. 15 Transmatic throttle linkage. Tilt cab models with 302 and 332 engines

Fig. 16 Hydraulic retarder linkage. Conventional cab models

Fig. 17 Hydraulic retarder linkage. Tilt cab models

8. Check adjustment by depressing pedal against its stop bolt. Retarder valve should be felt to bottom just before pedal hits the stop bolt.

Transmission, Remove and Replace

1. Loosen acorn nut on filter cover and drain transmission. When fluid stops flowing tighten filter cover nut.
2. On one-piece drive shaft models, disconnect shaft from pinion flange and from yoke at parking brake drum. *Do not remove the bolt that retains the flange on the transmission output flange.*
3. On two-piece drive shaft models, disconnect the coupling shaft from the yoke at the parking brake drum, then remove the center support bearing bracket. Move the forward end of the drive shaft out of the way.
4. Disconnect speedometer cable.
5. Remove fluid filler tube and breather hose.
6. Disconnect cable and TV rod from levers at transmission. Remove cable clamp bracket from housing.
7. Disconnect retarder linkage and remove cross shaft.
8. Disconnect parking brake linkage.
9. Remove fluid temperature warning light switch.
10. Disconnect oil cooler lines from fittings on retarder valve body, then remove forward fitting. Plug lines and valve body openings.
11. Remove flywheel housing dust shield.
12. Unfasten converter pump cover from flywheel (6 nuts).
13. Unfasten converter housing from frame cross member (2 bolts).
14. Remove nut from top of transmission rear support and cross member.
15. Raise rear of engine to take weight off cross member.
16. Support transmission with suitable jack.
17. Remove transmission rear support cross member.
18. Unfasten converter housing from flywheel housing.
19. Move converter and transmission away from engine until converter housing clears cross member, then lower the unit. If necessary, raise floor pan slightly to permit converter housing to clear cross member.
20. Reverse the foregoing procedure to install the transmission and check the adjustment of the linkage as outlined previously.

Rear Axle Section

For Eaton and Timken (Rockwell) driving axles used on Ford Trucks, see the "name" chapter for service procedures and lubricant capacities

SPICER INTEGRAL HOUSING TYPE AXLE

This rear axle, Fig. 1, is of the semi-floating, hotchkiss drive type. The drive pinion is the over-hung type, mounted on pre-loaded taper roller bearings. Sealing of the pinion shaft is accomplished at the front end by a spring-loaded leather seal bearing on the companion flange, which is splined and secured to the pinion shaft by a nut.

Axle Shaft, Remove

1. Raise vehicle and place stand jacks under rear axle housing.
2. Remove wheel and brake drum.
3. Remove four nuts from bearing retainer bolts on inside of axle flange.
4. Attach axle shaft puller, Fig. 2, and remove axle shaft and bearing assembly.
5. Install bolt and nut to hold brake backing plate on axle housing.

Bearing or Oil Seal, Replace

1. With a chisel, nick soft ring next to bearing and remove ring. The ring need not be split, only nicked deep enough to allow removal.
2. Install a suitable press plate between axle flange and bearing and press bearing from shaft.
3. To replace oil seal, pry it out of housing with screwdriver.
4. Install new seal.
5. Install new bearing, pressing it on so it seats on the shaft against shoulder. Bearing retainer must be on axle shaft before bearing is installed.
6. Install new bearing retainer ring, being sure ring seats against bearing.

Axle Shaft, Install

1. Insert five new bolts and force heads down to flange on new axle.
2. Peen end of shoulder on bolts into countersink around bolt holes in flange.
3. Install new bearing as outlined above.
4. Remove temporary nut and bolt holding brake backing plate in place.
5. Install new retainer gasket.
6. Install axle shaft in housing. Outer race of bearing must seat against shoulder in axle housing.
7. Install nuts and washers on bearing retainer bolts and tighten securely.
8. Install brake drum and wheel.

Rear Axle Assembly, Replace

Inasmuch as the axle tubes are pressed into the differential carrier to form a one-piece housing, the rear axle assembly must be removed from the chassis when it becomes necessary to overhaul the unit.

1. Raise vehicle from floor and support with stand jacks under frame side rails.
2. Remove rear wheels.
3. Split rear universal joint.
4. Disconnect parking brake cable from equalizer rod and unfasten brake cable brackets from frame cross member.
5. Disconnect hydraulic brake line connection at rear axle housing.
6. Loosen and move shock absorbers out of the way.
7. While supporting axle housing with hydraulic jack, remove spring clips and lower axle assembly to the floor.
8. Reverse the foregoing procedure to install the rear axle assembly, being sure to bleed the brake system when the installation is completed.

Fig. 1 Integral housing hypoid rear axle

Fig. 2 Type of puller used to remove semi-floating axle shaft

Fig. 3 Prying differential from housing

Differential Carrier, Disassemble

1. Remove axle shafts as outlined previously. Axle shafts may be pulled out only far enough to clear differential side gears.
2. Drain lubricant and rear cover.
3. Make sure differential side bearing caps and axle housing are marked, then remove the side bearing caps.

Fig. 4 Differential and pinion bearing adjustments

Fig. 5 Checking clearance between bearing cup and differential case

Fig. 6 Installing differential in housing

4. Pry differential from housing, Fig. 3.
5. Remove side bearing cups.
6. Pull off side bearing and adjusting shims, tagging the shims for identification on reassembly.
7. Unfasten ring gear from case.
8. Drive out differential pinion shaft pin and pull out the shaft, pinions and side gears.
9. Hold companion flange from turning and remove flange nut.
10. Pull flange from pinion shaft.
11. Remove pinion from carrier by tapping on front end with soft hammer.
12. Remove pinion shaft bearing oil seal and bearings from carrier, keeping separate the shim pack at each bearing.

Pinion & Bearings, Replace

If the original ring gear and pinion are being used in the original carrier, use the original shim packs at each bearing, Fig. 4. If a new pinion or differential carrier is installed, note the markings on the end of the pinion gear and on the differential carrier to obtain the correct thickness of shimming to be used with these parts from your supplier. The shims behind the rear bearing establishes the correct pinion depth.

1. Press the rear pinion bearing cup in the housing with the proper thickness of shims. Press the rear pinion bearing on the shaft.
2. Install the front bearing cup and shims, and front bearing.
3. Install the companion flange and, while holding the flange from turning, tighten the nut to a torque load of 200-220 lb. ft.
4. Check the pinion bearing pre-load with a spring scale and heavy cord wrapped around the companion flange. Pull on the spring scale. The torque required to rotate the pinion is 10-30 inch lbs. If not within these limits, add or remove shims from behind the front bearing to obtain the proper pre-load.
5. Remove the companion flange and install a new oil seal (well soaked). Reinstall the companion flange and tighten the nut to a torque load of 200-220 lb. ft.

Ring Gear, Replace

1. Install guide pins in every other hole in the ring gear. These pins can be made from 1½″ long capscrews with heads cut off and ends slotted.
2. Make sure back face of ring gear and face of case are free of dirt and burrs and slip gear over pilot diameter of case.
3. Install every other ring gear bolt. Draw them up evenly and snugly so ring gear face is flush with face of case.
4. Remove guide pins and install remaining bolts.

Differential Carrier, Assemble

The differential bearings are adjusted by shims, Fig. 4. These shims also establish the ring gear position with the

Fig. 7 Ring gear and pinion backlash adjustment

Fig. 8 Short heel contact. Move drive gear toward pinion

Fig. 9 Short toe contact. Move drive gear away from pinion

pinion. Therefore, backlash must be checked whenever a bearing adjustment is made.

The correct bearing adjustment is one which will provide a .015-.020″ pinch fit when the differential unit is assembled into the carrier. To make the adjustment, install the bearing cones without

Fig. 10 Contact too low and narrow. Pinion should be moved away from center of axle

Fig. 11 Contact too high and narrow. Pinion should be moved toward center of axle

Fig. 12 Correct tooth contact

shims and place the assembly in the housing with the bearing cups. Force the unit to one side and check the clearance between the bearing cup and differential case with a feeler gauge, Fig. 5. When the clearance is determined, select shims of this amount plus .015-.020″ extra to establish the proper preload.

Remove the differential bearings again and divide the shims into two packs of equal thickness and install on each side and replace the bearings. Reinstall the unit in the carrier. This operation is made easier by cocking the bearing cups slightly when the differential is placed in the housing and then tapping them lightly with a mallet, Fig. 6. However, when installing the differential in the housing, be sure the ring gear teeth mesh with the pinion teeth before tapping the bearings in place.

After the bearing cups are firmly in place, install the bearing caps. The bearing caps and gasket surface of the housing are marked with a horizontal numeral and on the other side by a vertical numeral. The position of the numerals should correspond when reinstalling the bearing caps.

Ring Gear & Pinion Backlash, Adjust

Mount a backlash gauge indicator on the carrier and start checking for the correct backlash between the ring gear and pinion. If the backlash is not within the limits of .004″ to .009″, it will be necessary to change the arrangement of the shims back of the bearings. Make corrections in backlash according to Fig. 7, bearing in mind that shims removed from one side must be installed on the opposite side so that the total shim thickness of the right and left side will remain unchanged, and the bearing adjustment undisturbed.

Gear Tooth Contact Pattern

Allowable variations in the carrier or drive pinion may cause the pinion to be too far in or out even when shimmed properly. Thus, the tooth contact must be tested and corrected as necessary or the gears may be noisy.

Paint the ring gear teeth with a light coating of red lead, white lead or prussian blue. Revolve the gears and observe the contact, referring to Figs. 8 to 12.

Fig. 13 Banjo type hypoid rear axle. 1957-63 F-100

FORD BANJO TYPE REAR AXLE

1957-63, F-100

This rear axle, Fig. 13, is a banjo-housing hypoid in which the drive pinion is mounted 2¼″ below the centerline of the drive gear. The drive pinion is straddle-mounted in that two opposed tapered roller bearings support the pinion shaft at the front of the pinion gear and a straight roller bearing supports the pinion shaft at the rear of the pinion gear.

The pinion shaft and gear are assembled in the pinion retainer which is bolted to the carrier housing. Two carrier and differential cases are used to accommodate two bearing sizes. The right and left axle shafts are not interchangeable since the left shaft is shorter than the right.

Disassembly

1. Mark one differential bearing cap and bearing support to ensure proper assembly. Remove adjusting nut locks, bearing caps and adjusting nuts. Lift differential out of carrier.
2. Remove drive gear from differential case.
3. Drive out differential pinion shaft retainer and separate the differential pinion shaft and remove gears and thrust washers.
4. Remove drive pinion retainer from carrier. Remove O-ring from retainer.
5. Remove pinion locating shim. Measure shim thickness with micrometer.
6. If the drive pinion pilot bearing is to be replaced, drive the pilot end and bearing retainer out at the same time. When installing, drive the bearing in until it bottoms. Install a new retainer with the concave side up.

7. Mount the drive pinion retainer assembly in a holding fixture and remove pinion shaft nut and flat washer. Then remove universal joint flange, oil seal and slinger.
8. Remove pinion retainer from fixture and place a protective sleeve or hose on the pinion pilot bearing surface. Then press the pinion shaft out of front bearing cone and remove spacer.
9. Remove pinion rear bearing cone.
10. Do not remove pinion bearing cups from retainer unless they are worn or damaged. The flange and pilot are machined by locating on these cups after they are installed in the bores. If new cups are to be installed, make sure they are seated in the retainer by trying to insert a .0015″ feeler gauge between cup and bottom of bore.

Assembly

Differential Case—Place a side gear and thrust washer in the differential case bore. *Lubricate all parts liberally with axle lubricant during assembly.* With a soft-faced hammer, drive pinion shaft into case only far enough to retain a pinion thrust washer and pinion gear. Place the second pinion and thrust washer in position. Drive the pinion shaft into place. Be careful to line up pinion shaft retainer holes. Place second side gear and thrust washer in position and install differential case cover. Install retainer. A pinion or axle shaft spline can be inserted in side gear spline to check for free rotation of differential gears.

Insert two $\frac{7}{16}$″ x 2″ bolts through differential flange and thread them 3 or 4 turns into the drive gear as a guide in aligning the drive gear bolt holes. Press or tap the drive gear into position. Install and tighten the drive gear bolts evenly and alternately across the gear to 60-65 lb. ft. torque.

If the differential bearings have been removed, use a suitable press to install them.

Pinion and Retainer—Install the pinion rear bearing cone on the pinion shaft and install a new spacer on the shaft. Place the bearing retainer on the pinion shaft, then install the front bearing cone. *As the bearing is pressed into position, rock the pinion retainer. Do not press the bearing on the shaft, until all play is removed between retainer and bearings as the spacer may be compressed too much.*

Lubricate both bearings with axle lubricant. Place oil slinger in position. Coat the outside edge of a new oil seal with an oil-resistant sealer and press it into the bearing retainer. New seals need not be soaked before installation. Install the universal joint flange. Place the flat washer over the pinion shaft and start the pinion shaft nut.

Hold the flange and tighten the pinion shaft nut until a torque required to turn the pinion is 8-12 *inch* lbs. with used bearings or 17-27 *inch* lbs. with new bearings. As the pinion shaft nut is tightened, rotate the pinion shaft frequently to allow the bearing to seat.

Shim Selection — Manufacturing tolerances in the pinion bore dimensions and in the best operating position of the gears make an adjustment shim necessary. This shim is placed between the pinion retainer and the carrier, Fig. 13. An increase in the thickness of the shim moves the pinion *away* from the drive gear. Manufacturing objectives are to make axles requiring a .0015″ shim and if a new assembly is being built, a .0015″ shim should be used for a tentative build-up. Shims are available in .010″ to .021″ thicknesses in steps of .001″.

Pinions and drive gears are marked, when matched, with the same number. Following the number on the pinion is a minus (—) or plus (+) followed by a number. If the pinion is marked "—1" it indicates that a shim .001″ thinner than a standard shim for this carrier is required. A minus number means the pinion should be moved closer to the drive gear and a thinner shim is required. A plus number means the pinion should be moved farther from the drive gear and a thicker shim is required. A pinion marked zero (0) is a standard pinion.

To select a shim, measure the original shim with a micrometer. Note the dimensional mark on the original pinion. Compare the mark on the original pinion with the mark on the new pinion to determine how the original shim should be modified.

For example, if the original shim is .015″ and the original pinion is marked "—1", the new pinion requires a +1 shim. Therefore, the new pinion requires a .002″ thicker shim, and a .017″ shim should be used. If the new pinion is marked the same as the old pinion, no shim change is required.

Backlash Adjustment—The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment and checking drive gear and pinion backlash is given in the *Rear Axle Service* chapter.

Four Wheel Drive Section

For service procedure on the transfer case used with four-wheel drive trucks, see the Transfer Case chapter

FRONT AXLE, 1959-63

The front axle on four wheel drive trucks is a single reduction Spicer type. For service procedure on the axle center, see the *Rear Axle Section* inasmuch as it is the same type as that which is used on the rear.

FRONT AXLE SHAFT

Removal

1. Raise truck on a hoist and then lower it so that the front axle is supported on a stand.
2. Referring to Fig. 1, remove hub dust cap and snap ring and slide splined driving hub from between outer axle shaft and wheel hub and drum.
3. After removing lock nut, washer and wheel bearing retaining nut from steering spindle, remove wheel, hub and drum as an assembly. The wheel outer bearing will be forced off the spindle at the same time.
4. Remove wheel inner bearing.
5. Place a drain pan under steering knuckle, and remove brake backing plate and spindle.
6. Pull outer axle shaft, universal joint and inner axle shaft from housing as an assembly.

Installation

Reverse the removal procedure to install the axle shaft. When installation is complete, remove the steering knuckle filler plug and fill the knuckle with ½ pint of the proper lubricant.

SPINDLE BEARING

Removal

1. Referring to Fig. 1, remove the inner and outer axle shafts and U-joint from each end of the axle housing.
2. Disconnect upper spindle arm from steering drag link (left side only).
3. Disconnect spindle connecting rod (tie rod) from front spindle arm.
4. Remove oil seal retaining bolts from rear flange of steering knuckle and remove the two-piece retainer.
5. Remove upper spindle arm (left side) and integral bearing cap and shaft from steering knuckle. On the right side there is only a bearing cap and shaft assembly. Remove bearing preload shims.
6. Remove lower spindle bearing cap and shaft from steering knuckle.

Fig. 1 Four wheel drive front axle assembly. 1959-63

7. Remove steering knuckle from axle housing yoke.
8. After removing upper and lower spindle bearings from the axle housing yoke, remove upper and lower bearing cups from yoke.
9. Remove felt, rubber and metal oil seal rings from axle housing.

Installation

Reverse the removal procedure to install the bearings. However, to mount the steering knuckle on the axle housing yoke, first fit the lower end of the knuckle over the bottom of the yoke so that the lower bearing will fit into the cup; then bring the entire knuckle into position on the yoke.

Place the bearing preload shims over the studs on the upper side of the knuckle and install the upper bearing cap and shaft. The shaft is inserted in the bearing and the cap is bolted to the upper side of the knuckle.

To check the bearing preload, place a torque wrench on one of the bearing cap nuts and pivot the knuckle on its bearings. As the knuckle is turned, a preload reading of 5 to 10 inch-pounds should register on the torque wrench. After removing or adding shims to establish correct preload, torque bearing cap nuts to 25 ft. lbs.

Steering Section

MANUAL STEERING GEAR

All Models

The worm and roller type steering gear assemblies used on all truck models are similar in design but differ in size and method of attachment to the truck frame. Fig. 1 shows a typical unit.

On all trucks except Cab Forward and Parcel Delivery models, the gear is mounted on the inside of the left frame side member. On Cab Forward and Parcel Delivery models, the steering gear is mounted on the outside of the left frame side member.

STEERING GEAR SERVICE

Adjustments, All Models

1. Disconnect Pitman arm.
2. Loosen mast jacket-to-instrument panel bracket.
3. Loosen steering gear mounting bolts.
4. Position mast jacket, if necessary, so that a $\frac{1}{16}''$ clearance exists between upper edge of mast jacket and shoulder of steering wheel.
5. Tighten all mounting bolts.
6. Loosen lock nut and turn sector shaft adjusting screw in a counterclockwise direction. This removes the load from the worm imposed by the close meshing of the roller and worm.
7. Turn steering wheel in one direction to the limit of its travel.
8. Using a spring scale hooked to the rim of the steering wheel, measure the pull required to keep the steering wheel rotating. The worm bearing pre-load is satisfactory if the effort required is ¼ to ¾ lb. on light duty trucks and a ½ to 1 lb. on other trucks.
9. If the pre-load is below the required limits, remove the shims from underneath the steering gear housing end plate, Fig. 1. Add shims if the pre-load is greater than the maximum allowable limit.
10. Turn the steering wheel from one extreme to the other, counting the total number of turns. Turn the wheel back exactly halfway to the center position.
11. Turn the sector shaft adjusting screw in a clockwise direction until all end play is removed from the sector shaft.
12. Using a spring scale, measure the effort required to turn the steering wheel through the center position. The final mesh adjustment should be as shown in table.

	F-100, F-250	350 thru 600	F-700 thru 1100; B-700, 750; C-550 thru 700; T-700 thru 850	C-750 thru 1100
Worm Bearing Pre-load (Pull to keep wheel moving—lbs.)	¼-¾	¼-¾	½-1	½-1
Worm to Roller Mesh (Pull through high point—includes worm bearing pre-load—lbs.)	1-2	1¼-2	1½-2½	1½-3

Service Note

On the heavy duty steering gear, Fig. 2, the worm sector roller mesh is adjusted by the use of shims between the sector thrust washers and the steering gear housing. This may be done with the steering gear mounted on the truck, provided the front splash shield is removed.

With the type steering gear shown in Figs. 3 and 4, the worm sector roller mesh is adjusted by removing the lock nut and turning the sector shaft adjusting screw in or out.

Steering Wheel, Replace

1. Disconnect horn wire at connector at bottom of gear case. On Tilt Cab models, connector is under instrument panel.
2. Press down on horn button and turn it counterclockwise to remove it.
3. Remove horn contact and wire from steering shaft.
4. Remove steering wheel nut and use a puller to remove the wheel.
5. Install the wheel with the single spoke of the wheel facing straight down when the front wheels are in the straight-ahead position.

Steering Gear, Remove Conventional Trucks

1. Remove the steering wheel.
2. Remove steering gear and brake pedal plate.
3. Unfasten steering column from instrument panel.
4. On F-7 and F-8 models, remove floor transmission cover plate, loosen engine rear mounting bolts, jack up transmission about 1¼", and remove engine oil dipstick and tube.
5. On all models, pull off Pitman arm.
6. Unfasten steering gear housing from frame.
7. Remove steering gear from underneath truck.

Tilt Cab Trucks

1. Remove the upper universal joint retaining nut and bolt.
2. Turn the wheel to the right and remove the Pitman arm.
3. Remove steering gear housing to frame bolts and remove the steering gear with universal joint attached.
4. Remove universal joint from the worm shaft.

Service Note

On some models it may be necessary to raise the front of the truck to remove the steering gear. It may also be necessary to remove oil filters or filter adapters to remove some steering gears.

Steering Gear, Disassemble

1. Drain lubricant from housing.
2. Remove sector shaft with housing cover.
3. Disassemble sector shaft from cover.
4. Remove steering gear housing end plate and tube assembly from housing.
5. Remove worm lower bearing and cup.
6. Loosen steering column clamp and remove tube and upper bearing from steering shaft.
7. Remove felt oil seal from top of gear housing.

Steering Gear, Assemble

If the sector shaft bushings are to be replaced, press the new bushings into the housing. The bushing nearest the oil seal should be flush with the inner edge of the grease retainer counterbore. The other bushing must be pressed in flush with the inside edge of the housing or housing cover, whichever applies. The needle bearing on gears so equipped should be installed flush with the outside surface of the housing cover. Burnish the bushings to the proper size.

Cover the serrations on the sector shaft with tape and carefully install a new grease retainer with the lips of the rubber facing inward toward the flow of grease.

Install the upper bearing cup and bearing in the gear housing. Slide the steering shaft and worm into the housing. Position the lower worm bearing cup, the same gaskets previously removed, and the steering gear housing end plate and tube assembly.

If new bearings have been installed, be sure to add new shims as necessary to give the proper pre-load. Tighten the cap screws. Install the felt seal over the steering shaft at the top of the gear housing.

Install the sector shaft and housing cover and tighten the cap screws.

Steering Gear, Install Conventional Trucks

1. Work from underneath the truck and position the gear assembly on the frame.
2. Install, but do not tighten, the bolts that secure the gear housing to the frame.
3. On gears which have a mounting bolt which can interfere with the movement of the steering gear arm, mount the bolt with its head on the outside of the frame.

Fig. 1 Typical steering gear assembly

Fig. 2 Heavy duty steering gear

4. Secure bracket to instrument panel, making sure rubber spacer is in place between bracket and column tube.
5. Tighten steering gear mounting bolts.
6. Install Pitman arm and tighten to a torque load of 170-180 lb. ft.
7. Install brake pedal plate and steering wheel.
8. Fill gear housing with lubricant and check for proper operation and adjustment.

Tilt Cab Trucks

1. Install woodruff key in the worm shaft if it fell out upon removal of gear.
2. Install universal joint.
3. Position steering gear housing on the frame side rail and install attaching bolts and nuts.
4. Have a helper push the steering shaft down until the woodruff key can be installed in the shaft.
5. Align the key with the slot in the universal joint, then push the shaft and key into the joint.
6. Install and tighten universal joint upper bolt and lock nut.
7. Install the Pitman arm, making sure the lock bolt slot lines up, and tighten to 180-220 lbs. ft.
8. Install horn wire brush in steering column.
9. Fill gear housing with lubricant and check for proper operation and adjustment.

POWER STEERING

F, B and T Models

The power steering system on these models, Fig. 5, consists of a pump and fluid reservoir, a control valve, a power cylinder, the connecting fluid lines and the steering linkage. The system used on Tilt-Cab models (see Fig. 10) differs in that a booster cylinder is used in place of the power cylinder installed on the other trucks.

The hydraulic pump, belt-driven by the engine crankshaft, draws automatic transmission fluid from the reservoir and provides fluid pressure for the system. Within the pump itself is a flow-control and pressure-relief valve which governs the pressures within the steering system according to the varying conditions of operation. After fluid has passed from the pump to the rest of the power steering system, it returns to the reservoir where it is filtered before returning to the pump.

The control valve, operated by steering wheel movement, directs the pressure developed by the pump. When the front wheels are in the straight-ahead position, the control valve spool is held in its center (neutral) position. Fluid then flows around the valve lands and returns to the reservoir.

When the steering wheel is turned to the left, the control valve spool moves toward the forward end of the valve. As a result, pressure from the pump is directed to the left-hand end of the power cylinder, and fluid from the right-hand end of the cylinder is directed back to the pump reservoir.

Fig. 3 One type of medium duty steering gear

Fig. 4 Another type of medium duty steering gear

A power-assisted right turn is made in the same way as the left turn except that when the steering wheel is turned toward the right, the control valve spool moves rearward. The fluid pressure from the pump acts against the right-hand face of the power cylinder piston, and the piston moves the steering linkage toward the left. *Should the pump fail to deliver fluid pressure, the truck may be steered without pump pressure.*

Fig. 5 Power steering system for F, B and T models

TROUBLE SHOOTING

Before performing any trouble shooting operations, check pump belt, fluid level, fluid leaks and turning effort.

Binding or Poor Recovery

If the steering wheel binds or sticks when turned, or if poor recovery to the straight-ahead position occurs, check the pitman shaft arm ball stud in the drag link outer sleeve. If binding is evident, make sure that the ball stud seats, spring and washer are properly installed.

Check the steering gear adjustments. The worm bearing preload and the worm and roller mesh adjustment should be within specifications.

Check the operation of the control valve spool in the valve housing. If the spool is binding in the housing, check the spool adjustment. If the adjustment is correct, overhaul or replace the control valve.

Check for interference between the sector shaft arm and the dust shield at the ball stud and, if necessary, replace the dust shield and/or ball stud.

Check the valve spool bolt lock nut adjustment. If the nut is drawn up too tightly, the ball stud will bind in the seats. Adjust the lock nut as required.

Check the control valve inner and outer sleeves for damage. Replace parts that show signs of damage, and adjust the valve spool lock nut.

Hard Steering

If the effort required to turn the steering wheel is greater than normal for the entire travel of the front wheels, perform a fluid pressure test (see Fig. 6). If the pump output pressure is low, and the pump belt is properly adjusted, the pump may be malfunctioning and should be overhauled.

If the pressure test shows that the trouble is in the control valve or power cylinder (booster cylinder on Tilt Cab models) remove and inspect these units. Repair or replace any damaged parts.

If the pressure test indicates that the pressures throughout the system are within specifications, check the following items in the order given:

Check the control valve spool for movement. If the spool does not move freely, check for and eliminate interference between the drag link outer and inner sleeves. If the spool is sticking in

Pump Type	Truck Model	Front Axle (Rated Capacity)	PRESSURES	
			Engine—Idling Wheels Straight Ahead Shut-Off Valve Open	Shut-Off Valve Closed
ROLL (with Bushings)	F-100, 250	2600	50-60 psi	900-1050 psi at 2500 Engine rpm
	F-350—600 P-350—500 B-500, 600	3800 thru 6000	60-70 psi	
	F, -B, -700 T-700 (292 V-8)	6000	55-65 psi	
ROTOR (With Ball Bearings)	F-, T-750—1100 C-850—1100 B-750 T-700 (332 V-8)	6000 thru 9000		
	F, -T, -800	11000		
ROLL (With Ball Bearings)	C-550, 700	6000 7000		1100-1300 psi at 1500 Engine rpm
	T-800	15000		
	F-, T-850, 950 F-1000, 1100 C-800—1100	11000 15000		

Fig. 6 Power steering pump applications and pressures

the housing, remove the spool and check the spool lands for burrs. Small burrs may be removed with crocus cloth provided the edges of the valve lands are not rounded in the process. If the spool cannot be repaired, replace the control valve.

Check the sector arm ball stud for free movement in the stud seats. If the ball is binding in the seats, adjust the drag link.

Excessive Free Play

If excessive free play or lost motion is noticed when steering, check the steering gear worm and roller mesh adjustment.

Check for excessive clearance between the sector arm ball stud and stud seats. If the stud is loose in the seats, adjust the drag link.

Noise

Check pump belt tension. If the belt is too tight, pump noise may result. A loose belt can cause belt squeal.

Noise may result if the specified hose is not used. If noise still exists with the proper hose installed, the pump should be removed and inspected.

Air in the system may also cause noise. To bleed the system, turn the wheels several times to each stop.

Steering Chatter

A loose pump belt can cause chatter against the wheel stops during an extremely sharp turn. Check and adjust belt tension.

Check for looseness in the spindle connecting rod connections. Looseness at this point may be due to low torque on the connecting rod ball stud or a worn adapter pin between the power cylinder and mounting bracket. Tighten the ball stud to specifications and replace any worn mounting parts.

Rattles

Check for looseness between sector arm ball stud and stud seats. If ball is loose in seats, adjust drag link.

Loss of Power Assist

Check the entire system for damaged or broken hoses. Replace or tighten a loose pump belt.

Perform a pressure test to determine whether the trouble is in the pump, the control valve or the power cylinder.

If the pressure test indicates that the pump is at fault, remove and repair the pump.

If the pressure test indicates that the control valve or power cylinder is at fault, check the following:

Disconnect the power cylinder piston rod from the spindle connecting rod. Operate the piston by hand to check for resistance to movement. If the piston moves easily with little or no resistance, the internal parts of the power cylinder are broken or damaged. Replace the power cylinder.

Check the operation of the control valve check valve. If the check valve does not operate freely, replace the check valve assembly.

FLUID PRESSURE TEST

A special pressure gauge assembly (tool No. T54L-33610-C) is available through the Ford Motor Co. for making this test.

Disconnect the pressure line hose from the pump outlet, and install the pressure gauge between the hose and pump outlet. *Be sure that the gauge is between the pump and shut-off valve on the tool.*

Open the shut-off valve on the tool and run the engine at idle speed. *If the pump normally operates quietly, ignore the louder pump noise when the pressure testing tool is connected to the system.* Allow at least two minutes for the fluid to warm up before starting the pressure checks.

1. Check the pressure with the wheels straight ahead (control valve in neutral). The pressure should not exceed the maximum neutral position pressure specified for the pump being checked, Fig. 6, with the engine operating at idle speed. If the pressure is higher, check the pump or control valve for faulty operation, or inspect the hoses, lines and connections for kinks and other obstructions.
2. Increase engine speed as indicated in Fig. 6 and then slowly close the gauge shut-off valve. If the pump is operating satisfactorily, the pressure should increase to the specified relief pressure range when the shut-off valve is fully closed. *Do not leave the shut-off valve closed for more than 15 seconds.*
3. If the pressure increases to more than the high limit of the relief pressure range, the pressure relief valve is not operating properly, and a pump overhaul is indicated.
4. If the pressure, with shut-off valve fully closed, is less than the minimum relief pressure, the trouble is in the pump. If the pressure increases to the specified relief pressure range, the trouble is in the control valve or power cylinder.

PUMP, REPLACE

100 Thru 600 (Except C) Models

1. To remove pump, remove reservoir cover.
2. Disconnect reservoir-to-pump hose.
3. Drain fluid from reservoir.
4. Disconnect pump-to-control valve hose from pump and fasten it in a raised position to prevent fluid from draining out.
5. Remove pump drive belt.
6. Remove pump.
7. Install pump in reverse order of removal. Fill reservoir to within one inch of top and install cover. Run engine at idle speed for about two minutes to warm the fluid. Turn steering wheel to both extremes several times and check for leaks. Increase engine speed to a fast idle and repeat.

Fig. 7 Pump housing and related parts

Models 700 Thru 1100 & C550, C600

1. Using a suction gun, remove as much fluid as possible through reservoir filler opening.
2. Disconnect pressure hose from pump and disconnect return line from cooler. Then fasten both hoses in a raised position to prevent fluid from draining out. *On C Series, the hoses can be more easily disconnected after the pump has been removed from its bracket and is resting on the frame member.*
3. Remove pump belt and pump.
4. When installing, check alignment of crankshaft pulley with pump pulley. If pulleys are not aligned, pump may be incorrectly installed, or it may be necessary to install spacers to align pulley.
5. When pump belt tension is correct, tighten adjusting bolt to 30-35 ft. lbs. Then tighten pivot bolt 20-25 ft. lbs. Tighten pump hose adapter to 30-35 ft. lbs.
6. Fill reservoir, start engine and run it at idle speed for two minutes. Then turn steering wheel to both extremes several times and check system for leaks.

PUMP REPAIRS

Disassembly

When disassembling the pump, lift the pump cover vertically from the housing to prevent the internal parts from falling out.

Before removing the parts from the pump housing, use a feeler gauge and a straight-edge to check the end clearance of the carrier and rollers in the housing, Fig. 7. If the clearance exceeds .0015", replace the worn parts. *A damaged roller, carrier or insert should not be replaced by itself; these parts are serviced in a kit and all parts of the kit should be used.*

Fig. 8 Control valve and drag link for light duty trucks

Inspection & Repairs

When all parts are disassembled, inspect the pump housing and cover for wear caused by turning of the rollers and the carrier. Check the carrier shaft bushings or bearings in the housing and cover for wear or scores. If bushings show wear or damage, replace the housing and/or cover. Replace the bearing or bushings if necessary.

Inspect the carrier, shaft and rollers for wear or any kind of damage. A damaged roller, carrier or insert should not be serviced alone; these parts are serviced in a kit and all parts of the kit should be used.

Be sure the valve and its bore are dry. Insert the valve in the housing and check for free movement of the valve in the bore. Remove any burrs with crocus cloth.

Inspect the carrier shaft seal in the pump housing for wear or damage. If there is damage or wear, carefully remove the seal with a punch, avoiding damage to the shaft bushing. *Remove the seal only when necessary.* Coat the lip of the new seal with Lubriplate or equivalent. *Position the seal in the bore with the lip facing toward the pump housing carrier chamber.* Press the seal into the housing until it seats firmly and evenly against the shoulder in the bore.

Assembly

During assembly, coat all parts with automatic transmission fluid.

If the carrier insert is to be replaced, the new insert must be installed so that the slot in the edge of the insert engages the small pin in the pump housing.

To avoid damaging the oil seal in the housing cover, carefully insert the shaft (with pulley attached) through the housing. Position the carrier shaft pin and slide the carrier onto the shaft.

When the pulley retaining bolt is properly tightened to a torque of 15-20 ft. lbs. the carrier shaft should turn freely.

When installing the reinforcement on the reservoir, the ears on the reinforcement should be facing upward over the outer hole in the reservoir.

When installing the reservoir cover, be sure the cover is seated evenly and tightly around the edge of the reservoir.

CONTROL VALVE, REPLACE

Models 100 Thru 600 (Except C550, C600)

To remove the control valve, disconnect the four hoses at the valve and drain the fluid from the hoses. Disconnect the studs from the spindle arm and sector shaft arm and remove the control valve and drag link.

Reverse the procedure to install the valve. Then fill the reservoir and operate the engine at idle speed for two minutes to warm the fluid. Increase engine speed to a fast idle and turn the steering wheel to both extremes several times to bleed the system of air and then check for leaks.

Models 700 Thru 1100 and C550, C600

1. Disconnect four hoses from control valve and drain fluid from hoses.
2. Remove dust cover from end of drag link outer sleeve.

Fig. 9 Control valve and drag link for heavy duty trucks

3. Unscrew ball plug from end of drag link sleeve.
4. Disconnect drag link from sector shaft arm ball stud.
5. Disconnect forward end of drag link from left spindle arm and remove control valve and drag link from truck.
6. Installation is made in the reverse order of removal.

CONTROL VALVE REPAIRS

Disassemble and assemble the control valve as indicated in Figs. 8 and 9.

When disassembled, clean all parts thoroughly and inspect them for wear or damage as follows:

1. Examine the lips of the seals for nicks or scratches that could allow fluid to escape from the control valve.
2. Examine the control valve spool for burrs and scoring. Remove burrs with crocus cloth. *Do not round off the sharp edges on the spool as the operation of the valve may be affected.*
3. Inspect control valve housing for burrs, scores or damaged surfaces. Remove burrs with crocus cloth.
4. Dry valve spool and housing thoroughly and insert spool in housing. Spool should fall freely of its own weight through housing.
5. Inspect mating surfaces of drag link inner and outer sleeves for wear or damage. Minor burrs or scores may be removed with crocus cloth. Check the fit of the inner sleeve in the outer sleeve. The inner sleeve should slide freely in the outer sleeve.
6. Check the drag link ball stud seats and spring for wear or damage.

Fig. 10 Power steering installation on Tilt Cab models

POWER CYLINDER

1. To remove, disconnect control valve-to-power cylinder hoses at power cylinder. Fasten ends of hoses in a raised position to prevent fluid drainage.
2. Disconnect parts from end of spindle connecting rod end of power cylinder.
3. At the anchored end of the cylinder, remove nut, pin and two bushings. Then remove power cylinder from truck and drain fluid.

Inspection

Clean outside of cylinder and wipe parts dry. Inspect the cylinder and piston for wear or damage. The internal parts of the cylinder, except the seals and hose seats, and the rod cannot be repaired or replaced. If either the cylinder or rod is worn or damaged, or if the piston is leaking internally, the entire power cylinder assembly must be replaced as a unit. The cylinder seals and seats are replaceable.

Inspect the mounting bushings and insulators for wear or damage and replace as necessary.

Seal Replacement

Install all parts contained in the seal kit. Clamp the cylinder in a vise and remove the snap ring from the end of the cylinder. Pull piston rod out all the way to remove the scraper, bushing and seals. Lubricate the inner seal with automatic transmission fluid. Then place seal, bushing, outer seal and scraper on the piston rod. Push the rod in all the way and install the parts in the cylinder with a deep socket slightly smaller than the cylinder opening. Install snap ring in end of cylinder.

Hose Seat, Replace

If either hose seat is worn or damaged both seats should be replaced.

Tap the hole in the power cylinder hose seat with a 3/8" starting tap. *Be sure to remove all metal chips from the hole after tapping.*

Place a nut and flat washer large enough to cover the seat port on a 3/8" bolt, then thread the bolt into the tapped hole and turn the nut to pull the seat out of the port.

Position the new seat in the port and thread a 5/8-18 bolt into the port until the seat bottoms in the port.

C SERIES BOOSTER CYLINDER

The booster cylinder on Tilt Cab models drives the intermediate pitman arm which in turn drives the rear drag link, spindle arm and spindle connecting rod. Fig. 10.

Removal

1. Tilt cab forward and drain cooling system.
2. Remove fan and radiator.
3. Disconnect idler arm from steering sector shaft.
4. Place drain pan under cylinder and disconnect left and right turn lines from cylinder.
5. Unfasten and remove cylinder from truck.

Disassemble

1. Remove front-to-rear end plate tube and drain fluid from cylinder.
2. Remove sector shaft bushing support plate from side of cylinder.
3. Remove sector shaft and thrust washer from housing.
4. Remove cylinder end plates, then

reach into support plate opening and push pistons out of cylinder.

5. Remove sector shaft seal snap ring and remove seal.

Inspection

Clean and wipe all parts dry. Blow out all passages and grooves with compressed air. Discard all seals and install new ones upon assembly.

Inspect cylinder bore for nicks, scores and scratches which could allow fluid to leak past the piston rings. Touch up minor damage with crocus cloth, but discard the entire assembly if the bore is not fit for service. *The cylinder housing is not available as a service part. If the housing is damaged beyond repair, the entire booster cylinder must be replaced.*

Inspect piston rings for scores on the contact face. Replace worn rings. Check ring side clearance in the groove. Clearance should be .002-.004″. If side clearance exceeds .004″, replace the piston and install a new set of rings.

Check sector shaft bushings. One bushing is located in the cylinder housing, the other is in the bushing support plate. Bushing-to-sector shaft clearance should be .0005″ to .0025″. Replace bushings if clearance is excessive.

Check sector shaft for burred or broken pinion teeth, and for rough spots on the bushing and seal contact surfaces. If the shaft cannot be cleaned up and made serviceable with crocus cloth, replace the sector shaft.

Inspect end plates, bushing support plate, and cylinder housing for nicks and burrs on the mating surfaces. Dress rough spots with a fine file. Inspect tube connector seats in housing and end plates. *If seats are damaged in any way, replace them in the same manner outlined for the power cylinder on other trucks.*

Check sector shaft thrust washer thickness, which should be .058-.062″. If it is worn to less than .058″, a new washer should be installed.

Assemble

Assemble the cylinder in the reverse order of disassembly, being sure to note the following:

1. Lubricate parts with automatic transmission fluid during assembly.
2. Sector shaft seal is positioned in bore in cylinder with metal side of seal facing outward. Install seal snap ring.
3. When installing piston rings, make sure ring gaps are staggered and use a piston ring compressor tool when installing the piston.
4. When installing the cylinder racks, the two center teeth on each rack are identified by "X" marks. The upper and lower center teeth on the sector shaft pinion are also identified by "X" marks. Position the pistons in the cylinder so that the "X" marks are aligned when the sector shaft is installed.
5. Place the sector shaft thrust washer in the cylinder housing. Install the sector shaft with the serrations facing down and with the "X" marks properly aligned.
6. When assembled, tighten the end plate bolts to a torque of 12-15 ft. lbs. When the front-to-rear end plate connector tube is installed, tighten the fittings to 30-40 ft. lbs.

Installation

Reverse the removal procedure to install the booster cylinder. Tighten the hydraulic line fittings to a torque of 30-40 ft. lbs. Fill the cooling system. Fill the reservoir with automatic transmission fluid. Start the engine and turn the steering wheel one full turn to the right and to the left to fill the booster cylinder and lines. Stop the engine and refill the reservoir. Then start the engine and check for leaks after making another full right and left turn.

Engine Section

ENGINE, REPLACE

1. Support engine compartment cover in raised position.
2. Drain cooling system and oil pan and remove air cleaner.
3. Disconnect usual items such as wires, hose, fuel and vacuum lines, carburetor linkage, etc.
4. Raise truck on hoist.
5. Remove propeller shaft.
6. Disconnect linkage at transmission.
7. Remove clutch equalizer bar and its mounting bracket.
8. Remove exhaust pipe, muffler and tail pipe as a unit.
9. Lower truck halfway down for safety in removing engine.
10. Support engine with jack.
11. Unfasten engine rear support from transmission extension housing and hanger bracket.
12. Lower jack and engine from truck.

CYLINDER HEAD, REPLACE

1. Drain cooling system, remove air cleaner and disconnect battery cable at cylinder head.
2. Disconnect exhaust pipe at exhaust manifold.
3. Disconnect carburetor linkage, fuel and vacuum lines, water hoses and wires from spark plugs.
4. Remove rocker arm cover.
5. Back off valve adjusting screws to remove load from rocker arms. Then remove rocker arm shaft assembly.
6. Remove valve push rods, keeping them in proper sequence so they are returned to proper locations.
7. Remove one bolt from each end of cylinder head at opposite corners and install cylinder head guide studs ($\frac{7}{16}$"-14 x 6").
8. Remove remaining bolts and lift off cylinder head.
9. Reverse above procedure to install the cylinder head and tighten bolts in three progressive steps as follows: Tighten bolts in the sequence shown in Fig. 1 to 55 ft. lbs. torque; then tighten them to 65 ft. lbs. Finally, tighten them to 75 ft. lbs. *Once bolts have been tightened to specifications, they should not be disturbed.*

VALVE ARRANGEMENT

Front to rear . . . E-I-I-E-I-E-E-I-E-I-I-E

Fig. 1 Head tightening sequence

Cross section of engine

VALVES ADJUST

Before the final valve lash adjustment is made, operate the engine for 30 minutes at a fast idle to stabilize engine temperatures. To set the lash accurately, use only a step-type feeler gauge. For example, to obtain the correct setting if the clearance is .016", the .015" portion of the gauge ("go") should enter but the "no go" end (.017") should not enter.

Before starting the adjustment procedure, make two chalk marks on the crankshaft pulley. Space the marks approximately 120° apart (⅓ of circumference) so that with the timing mark the pulley is divided into three equal parts. Adjust the valves for No. 1 cylinder. Repeat the procedure for the remaining valves, turning the crankshaft ⅓ turn in the direction of normal rotation while adjusting the valves in the firing order sequence of 153624.

VALVES REMOVE

After taking off the head as outlined previously, proceed as follows:

1. Remove capscrews retaining rocker shaft brackets to head and remove shaft assembly.
2. Clean carbon out of combustion chambers before removing valves.
3. Compress valve springs with a suitable spring compressor, remove valve stem locks and release the springs. Remove sleeve, valve spring cap retainer, spring and valve. Discard intake valve seals, Fig. 2.
4. Place valves in a board with numbered holes so they can be replaced in their original positions upon reassembly.

VALVES GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{1}{32}$", otherwise the valve must be replaced.

Inspect the valve seats in the head for cracks, burns, pits, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition.

VALVE GUIDES

Valve guides in these engines are an integral part of the head and, therefore, cannot be removed. For service, guides can be reamed oversize to accommodate one of three service valves with oversize stems (.003", .015" and .030").

Fig. 2 Valve assembly

Check the valve stem clearance of each valve (after cleaning) in its respective valve guide. If the clearance exceeds the service limits of .004″ on the intake or .005″ on the exhaust, ream the valve guides to accommodate the next oversize diameter valve.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 3. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16″, and since the acceptable valve head margin is approximately 1/16″ to 3/32″, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, *the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.*

Fig. 3 Checking installed height of valve spring

VALVE SPRING TESTING

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 4, and according to the specifications given in the *Valve Data Chart.* If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

Fig. 4 Checking valve spring pressure

ROCKER ARMS REPLACE

1. To disassemble, remove pin and spring washer from each end of rocker shaft, Fig. 5.
2. Slide rocker arms, springs and supports off the shaft, being sure to identify location of parts for reassembly.
3. If it is necessary to remove the plugs from the shaft ends, drill or pierce the plug on one end. Then use a steel rod to knock out the plug on the opposite end. Working from the open end, knock out the remaining plug.

Fig. 5 Rocker arm shaft assembly

Fig. 6 Removing valve lifter using magnet rod

Assemble

1. Lubricate all parts with engine oil. Apply Lubriplate to the rocker arm pads.
2. If plugs were removed from shaft ends, use a blunt tool or large diameter pin punch and install a plug (cup side out) in each end of shaft.
3. Install spring washer and pin on one end of shaft.
4. Install rocker arms, supports and springs in order shown in Fig. 5. *Be sure oil holes in shaft are facing downward.*
5. Complete the assembly by installing remaining spring washer and pin.

VALVE LIFTERS, REPLACE

When necessary to replace the lifters, remove the cylinder head and related parts as outlined previously. Using a magnet, remove and install one lifter at a time, Fig. 6.

When installing, apply Lubriplate to each lifter foot and coat the remainder of the lifter with engine oil before installation.

TIMING CASE COVER

1. To remove cover, drain cooling system.
2. Remove radiator, fan and pulley, and crankshaft pulley.
3. Remove cover and gasket (crankcase ventilation tube bracket is retained by one cover bolt).
4. *If oil pan gasket is broken or damaged during front cover removal, drop the oil pan and install a new gasket.*
5. To replace the cover oil seal, drive out the seal with a pin punch and clean out the recess. Coat a new seal with grease and install the seal, driving it in until it is fully seated in cover recess. Check the seal after installation to make sure the spring is properly positioned in the seal.

TIMING CHAIN

After removing the cover as outlined above, remove the crankshaft front oil slinger. Crank the engine until the timing marks are aligned as shown in Fig.

7. Remove camshaft sprocket retaining bolt and washer. Slide both sprockets and chain forward and remove them as an assembly.

Reverse the order of the foregoing procedure to install the chain and sprockets, being sure the timing marks are aligned.

CAMSHAFT REPLACE

To remove camshaft, remove cylinder head and related parts, radiator, oil pan, timing chain cover and valve lifters.

Remove timing chain and sprockets, camshaft thrust plate, and pull camshaft out of engine. If thrust plate shows signs of wear, install a new one.

Fig. 7 Timing marks aligned for correct valve timing

CAMSHAFT BEARINGS REPLACE

To install new bearings it will be necessary to remove the engine from the vehicle. Bearings are available pre-finished to size and require no reaming for standard and .015″ undersize journal diameters. Number 4 bearing is not interchangeable with the other bearings.

1. After removing the engine, remove the camshaft and rear bearing bore plug.
2. Remove camshaft bearings, Fig. 8.
3. To install, position the bearing at the bearing bore and press it in place. *No. 1 bearing must be pressed in .100-.140″ below front face of bearing bore. Press the remaining bearings in sufficiently to align the oil supply holes.*
4. Clean camshaft rear bearing bore plug recess and install a new plug.
5. Install parts removed and install engine in car.

PISTONS & RODS REMOVE

After removing the cylinder head and oil pan, use a ridge reamer to remove any ridge that may have formed on the cylinder wall at the top of the piston ring travel. Cutting the ridge before the piston is removed will avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod cap and push the piston and rod out through the top of the bore. Use care to prevent the rod from nicking crankshaft journals. Identify the connecting rods (original rods are marked) when removing them so they may be installed in their original cylinder.

PISTON & ROD ASSEMBLE

When installed, piston and rod assembly should have the notch in piston head toward front of engine with oil squirt hole in rod positioned as shown in Fig. 9.

PISTONS

Pistons are available for service replacement in standard sizes and oversizes of .020″, .030″, .040″ and .060″.

If the pistons are to be re-used with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an oil piston ring. File the broken end to a sharp, square edge and use it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe

Fig. 8 Camshaft and related parts

Fig. 9 Piston and rod assembly

Fig. 10 Piston clearance chart

off the carbon on the sides of the piston. *Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands.* Pistons showing scuffed or scored skirts should be discarded for new ones. Examine the ring lands carefully for cracks. If in the least bit doubtful, the piston should be scrapped.

New pistons should be fitted according to the recommendations given in Fig. 10.

PISTON PINS

The piston pin bore of the connecting rod must be within the limits of .9107-.9112". The diameter of the piston pin must be within the limits of .9120-.9123".

Apply a light coat of engine oil to all parts. Assemble the piston to the connecting rod as shown in Fig. 9. Start the piston pin in the piston and connecting rod. Use the equipment shown in Fig. 11 and draw the pin through the piston and rod until end of pin seats in Detail 2, Fig. 11. If this equipment is not available, the pin may be installed with a suitable press.

PISTON RINGS

New rings should be assembled on the piston according to the instructions furnished by the ring manufacturer. Always use standard size rings in cylinder bores that are *standard at the bottom, regardless of the amount of cylinder wear.*

When new rings are installed without reboring cylinders the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves are worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in bore by tapping with the lower end of the piston. Then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of the rings carefully with a smooth file.

Fig. 12 Checking rod bearing clearance with Plastigage

Fig. 11 Piston pin installation

ROD BEARINGS

These bearings are of the insert type, selectively fitted, and available for service replacement in standard and undersizes for use on crankshaft journals that have been reground.

If inspection reveals badly worn or scored bearings, they should be replaced. Bearings may be removed by simply taking off the bearing caps and slipping the old ones out and the new ones in. The installation of new bearings must be closely checked to maintain the proper clearance between the crankshaft and bearing surface. A convenient and accurate method for checking bearing clearance is with the use of Plastigage, which is available at any auto parts jobber.

Place the string-like plastic material so it extends the full width of the bearing, Fig. 12. Install the bearing and cap and tighten the nuts to the recommended torque which is listed in the *Engine Torque Specifications* chart. Then loosen the nuts and carefully remove the cap and bearing. The widest portion of the Plastigage is then measured with the scale on the Plastigage envelope. The graduation on the envelope corresponding to the thickness of the Plastigage gives the bearing clearance in thousandths of an inch.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005" to .015" cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell, Fig. 13.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Torque* table.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding end of the seal with sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced, it is possible to do the job without removing the crankshaft as follows:

To remove the old seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being moved.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over 3/8" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is being installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

Fig. 13 Crankshaft and related parts

OIL PAN, REPLACE

1. Drain oil pan and remove oil level dipstick.
2. Remove pan attaching bolts and rotate engine as required to gain clearance and drop oil pan.
3. Remove oil pump inlet tube and screen.

OIL PUMP REPLACE

1. Remove oil pan as directed above.
2. Remove pump pick-up tube and screen.
3. Unfasten and remove pump from engine.
4. Reverse order of removal to install.

OIL PUMP REPAIRS

Referring to Fig. 14, disassemble pump. To remove the oil pressure relief valve, insert a self-threading sheet metal screw of the proper diameter into the oil pressure relief valve chamber cap and pull cap out of chamber. Remove spring and plunger.

The inner rotor and shaft and the outer race are serviced as an assembly. One part should not be replaced without replacing the other.

Install the pump cover and tighten to 6-9 ft. lbs. torque.

RADIATOR

1. Working from inside truck, remove engine access cover.
2. Drain cooling system.

Fig. 14 Oil pump assembly

3. Disconnect hoses from radiator.
4. Remove radiator support bolts.
5. From driver's seat, back out two bolts that attach engine compartment front end panel to side panel. This permits radiator to be rotated and removed.

WATER PUMP REPLACE

Drain cooling system and remove lower hose at water pump. Remove drive belt, fan and water pump pulley. Disconnect heater hose at water pump. Unfasten and remove water pump.

WATER PUMP REPAIRS

To disassemble pump, refer to Fig. 15 and remove hub from impeller shaft. Press shaft and bearing out of housing. Remove impeller from shaft.

To assemble, clean all gasket material from pump. If a new shaft is used, install the slinger on the shaft in the same relative position as the old slinger. Coat the bearing outer diameter with grease and press the shaft into the housing. Apply a light film of waterproof sealer on a new seal and press seal into housing. Install impeller. Lightly coat seal rubbing face of impeller with grease, then press shaft onto impeller.

Press shaft into impeller just far enough so that pump housing lightly touches face of adapter ring. The impeller-to-pump body clearance should be 005-025" after impeller is installed.

Press water pump onto shaft until there is $3\frac{15}{16}$" from gasket surface to outside surface of pump hub.

Engine lubrication diagram. 6-144 and 6-170 engines

Fig. 15 Water pump assembly

DISTRIBUTOR REPLACE

1. To remove the distributor, disconnect the primary wire and vacuum control pipe.
2. Remove distributor cap.
3. Scribe a mark on the distributor body indicating the position of the rotor, and scribe another mark on the body and engine block indicating position of distributor body in block. These marks can be used as guides when installing distributor in a correctly timed engine.
4. Remove hold down screw or screws and lift distributor out of block. *Do not crank engine while distributor is removed or the initial timing operation will have to be performed.*

Installation

If the crankshaft has not been disturbed, install the distributor, using the scribed marks previously made on the distributor body and engine block as guides.

If the crankshaft has been rotated while the distributor was removed from the engine, it will be necessary to retime the engine. Crank the engine to bring No. 1 piston on top dead center of its compression stroke. Align the timing mark on the crankshaft pulley with the timing pointer (see *Tune Up* chart). Install the distributor so that the rotor points to the No. 1 spark plug wire terminal in the distributor cap.

Make sure the oil pump intermediate shaft properly engages the distributor shaft. It may be necessary to crank the engine with the starter, after the distributor drive gear is properly engaged, in order to engage the oil pump intermediate shaft.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

STARTER REPLACE

Disconnect cable at starter. Unfasten and remove starter and rubber dust ring.

When installing the starter snug all bolts, then tighten them starting from the middle bolt.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasket surfaces. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A stuck valve in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work in the oil. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter.*

FORD & HOLLEY CARBURETOR ADJUSTMENTS

Year	Model	Carb. Type	Idle Adjustments					Float Level	Fuel Level	Float Bowl Vent Valve	Pump Override Spring	Choke Unloader	Choke Setting

Fig. ②—Fuel level measured from power valve mounting surface.

Fig. ③—Measure from bottom of float to air horn, with air horn inverted.

Clutch & Transmission Section

CLUTCH

Pedal Free Travel

Clutch pedal free travel should be 7/8" to 1 1/8". If not within these limits, loosen nut on turnbuckle on clutch release rod and adjust turnbuckle as required to obtain correct free pedal travel.

Clutch, Replace

1. Remove starter motor.
2. Remove transmission.
3. Disconnect clutch release lever retracting spring and release rod.
4. Remove clutch release bearing and hub.
5. Remove flywheel housing and dust cover.
6. Remove clutch from flywheel.
7. Reverse removal procedure to install and adjust clutch pedal free travel.

TRANSMISSION

Transmission, Replace

1. Raise truck on hoist.
2. Remove drive shaft.
3. Disconnect speedometer cable.
4. Disconnect gearshift rods from transmission shift levers.
5. Position jack under engine and remove transmission rear support anchor bolt.
6. Lower engine enough to drop transmission extension housing from hanger bracket.
7. Unfasten transmission from flywheel housing and remove.
8. Reverse removal procedure to install transmission.

1963 TRANS. REPAIRS

1963 V8s

1. To disassemble the transmission, Fig. 1, remove bottom drain plug and drain lubricant.
2. Remove parts shown in Fig. 2.
3. Remove filler plug from right side of case and drive out the countershaft retainer, Fig. 3. Lower countershaft assembly to bottom of case.
4. Lift input shaft gear and shaft from front of case, being careful not to drop needle bearings from bore of input shaft.
5. Slide speedometer drive gear from mainshaft and remove the drive gear lock ball from shaft.
6. Use a suitable puller to remove mainshaft rear bearing.
7. Place both shift levers in neutral position.
8. Remove plug that retains detent plunger and spring in case and remove these parts, Fig. 4.
9. Remove shift fork components.
10. Lift mainshaft assembly out through top of case.
11. Working through front bearing opening, drive reverse idler gear shaft out through rear of case with a drift. Then lift reverse idler gear and two thrust washers from case.
12. Lift countershaft and thrust washers from case, using a dummy shaft to hold needle bearings in place.
13. Remove shift levers and shafts, Fig. 5.
14. Remove snap ring from front end of mainshaft and slide synchronizer and second speed gear off shaft.
15. Remove snap ring and thrust washer from mainshaft and slide first speed gear and blocking ring off shaft.
16. Remove the next snap ring and slide reverse gear and sleeve from shaft.
17. Remove dummy shaft, needle bearings and two retainer washers from countershaft gear.
18. Disassemble synchronizers.
19. Assemble the transmission in the reverse order of disassembly, referring to Figs. 2 through 10. Countergear and reverse idler gear end play should be .004 to .018". Replace thrust washers as required to obtain this end play.

Fig. 8 Front synchronizer disassembled

Fig. 7 Mainshaft disassembled

Fig. 9 Rear synchronizer disassembled

Fig. 11 Transmission disassembled. 1961-62

1961-62 TRANS. REPAIRS

1. Referring to Fig. 11, remove gearshift housing. Lift shift forks from gears.
2. Remove 4 extension housing bolts.
3. Remove input shaft bearing retainer.
4. Slide input shaft forward to disengage from synchronizer.
5. Slide synchronizer and 2nd speed gear forward to disengage the latter from cluster gear.
6. Remove extension housing and mainshaft.
7. Remove synchronizer hub snap ring from mainshaft and remove synchronizer, 2nd gear and sliding gear.
8. Remove mainshaft bearing snap ring from extension housing and remove housing.
9. Remove speedometer gear and ball from mainshaft.
10. Using brass drift, drive reverse idler shaft and roll pin out of case. Lift gear from case.
11. Drive countershaft rearward out of case and allow cluster gear to fall in case.
12. Remove input shaft assembly.
13. Lift out cluster gear.
14. Reverse disassembly procedure to assemble transmission, referring to Fig. 11.

Fig. 10 Countershaft disassembled

Gearshift Linkage, Adjust

If transmission shifts hard or if it will not engage, the gearshift levers require adjustment at the cross-over. Move shift lever through all positions. If cross-over is not smooth, adjust as follows:

1. Loosen trunnion nuts at transmission shift levers to allow shift rods to slide freely in their trunnion.
2. Insert a ¼″ rod through pilot hole in shift tube floor-mounted bracket until it enters adjustment hole of both upper and lower shift lever.
3. Place transmission shift lever in neutral and tighten trunnion nuts.
4. Remove ¼″ rod and check transmission operation in all shift positions.

Rear Axle, Brakes & Steering

Fig. 1 Rear axle disassembled

REAR AXLE

All operations on the differential case assembly and drive pinion assembly may be performed with the axle housing in the truck, Fig. 1.

Differential & Pinion, Remove

1. Remove axle shafts as outlined further on.
2. Remove axle housing cover.
3. Remove drive shaft.
4. Mark one differential bearing cap and case so marks can be matched on reassembly.
5. Remove differential bearing adjusting nut locks, cap bolts and bearing caps.
6. Lift out differential.
7. Remove drive pinion flange nut and flange. With soft-faced hammer, drive pinion out of front bearing cone and remove it through rear of carrier casting.
8. Drive against front pinion bearing cone and drive flange seal and bearing cone out of front of carrier casting.
9. If they are to be replaced, drive pinion bearing cups out of casting with a drift. *When installed, make sure cups are properly seated in their bores. If a .0015" feeler gauge can be inserted between cup and bottom of its bore at any point around cup, cup is not properly seated.*
10. Remove pinion rear bearing cone. *Measure shim (under bearing cone) with a micrometer and record its thickness. If a new gear set is installed on reassembly, a new shim will have to be installed.* The original shim thickness is one of the factors necessary in calculating the new shim thickness.
11. Remove differential components from case.

Drive Pinion Adjustment

Referring to Fig. 1, assemble drive pinion and related parts in housing. In replacing a drive gear and pinion, it should be noted that the original factory installed shim is of the correct thickness to adjust for individual variations in both the carrier casting dimension and in the original gear set dimension. Therefore, to select the correct shim thickness for the new gear set, proceed as follows:

1. Measure thickness of original shim with micrometer.
2. Note shim adjustment number on both the old pinion and the new pinion.
3. Refer to Fig. 2 to determine the correct amount of shim thickness change.
4. If the original shim pack was lost or if a new carrier casting is being installed, substitute a nominal .018" shim for the original and follow the foregoing procedure for a trial build-up. If any further shim change is necessary it will be indicated in the tooth pattern check which is described in the *Rear Axle Chapter.*

Pinion Bearing Preload

1. Insert flange into seal and hold it firmly against front bearing cone. Insert pinion shaft into flange.
2. Place flat washer on pinion shaft, start and tighten flange nut. While there is still end play in pinion shaft, flange and cone will be felt to bottom as nut is tightened.

3. From this point a much greater torque must be applied to turn the nut since the spacer must be collapsed. Also, from this point, the nut must be tightened very slowly and pinion shaft end play checked so that pinion bearing preload does not exceed specified limits. *If preload exceeds limits, a new collapsible spacer must be installed.*
4. As soon as there is preload on the bearings, turn pinion shaft in both directions several times to seat bearing rollers.
5. Adjust preload on used bearings to 10-16 inch lbs. torque and 17-27 inch lbs. on new bearings. Preload is measured with an inch-lb. torque wrench on flange nut as nut is tightened.

Old Pinion Marking	New Pinion Marking								
	−4	−3	−2	−1	0	+1	+2	+3	+4
+4	+0.008	+0.007	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0
+3	+0.007	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0	−0.001
+2	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0	−0.001	−0.002
+1	+0.005	+0.004	+0.003	+0.002	+0.001	0	−0.001	−0.002	−0.003
0	+0.004	+0.003	+0.002	+0.001	0	−0.001	−0.002	−0.003	−0.004

−4	0	−0.001	−0.002	−0.003	−0.004	−0.005	−0.006	−0.007	−0.008

Fig. 2 Drive pinion shim thickness changes

Backlash and Differential Bearing Preload

Check backlash of ring gear and pinion and gear tooth contact as described in the *Rear Axle Chapter*. To establish differential bearing preload, proceed as follows:

1. Tighten differential bearing cap bolts to 40-50 ft. lbs. torque to be sure bearing cups and adjusting nuts are seated. Then loosen cap bolts and re-torque them only to 5 ft. lbs. before making adjustments.
2. Loosen right-hand adjusting nut until it is away from cup. Then tighten left-hand nut until ring gear is forced into pinion with no backlash. Tightening left-hand nut decreases ring gear and pinion backlash and tightening right-hand nut increases backlash.
3. Loosen left-hand nut 1 to 1½ notches. Then tighten right-hand nut two notches beyond the position where it first contacts bearing cup. Rotate ring gear several revolutions in each direction while bearings are loaded to seat the bearings in their cups.
4. Again loosen right-hand nut to release preload. If there is any backlash between gears tighten left-hand nut just enough to remove this backlash.
5. At this time, make sure that one of the slots in the left-hand nut is so located that the lock can be installed without tightening the nut. Carefully tighten the right-hand nut until it just contacts the bearing cup. Then set the preload by tightening the right-hand nut 2 to 3 notches tight.

Axle Shaft, Replace

1. Remove wheel and tire.
2. Back off rear brake shoe adjustments and remove brake drum.
3. Working through hole provided in axle shaft flange, remove nuts that secure wheel bearing retainer. Then pull axle shaft out of axle housing with a slide hammer type puller. *The brake carrier plate must not be dislodged; install one nut to hold plate in place after axle shaft is removed.*
4. If the rear bearing is to be replaced, loosen the inner retainer, Fig. 1. The retainer will become loose on the shaft if it is nicked deeply in several places with a chisel.
5. Remove bearing from shaft, using a press or puller. The new bearing should be pressed on the shaft so that it seats firmly against the shoulder on the shaft. Then press the retainer on the shaft until the retainer seats firmly against the bearing.
6. If the axle shaft oil seal is to be replaced, remove the seal with a slide hammer tool and install the new seal with a suitable driver.
7. Reverse the above procedure to install the axle shaft.

BRAKES, ADJUST

The brakes should be adjusted when the drums are set at normal room temperature. If shoes are adjusted when drums are hot, dragging brakes may result when drums cool.

1. Referring to Fig. 3, raise truck until wheels clear floor. *If truck is on a frame contact hoist, disconnect parking brake cables to prevent their tightening when rear axles and springs sag.*
2. Remove adjusting hole cover from bottom of brake carrier plate and turn adjusting screw until a slight drag on wheel is noted.
3. Back off adjustment 10 notches to allow wheel to rotate freely.
4. Repeat on other wheels.

MASTER CYLINDER, REPLACE

1. Raise front end of truck and position safety stands.

Fig. 3 Brake assembly (front)

Fig. 4 Steering gear and column assembly

2. Remove forward splash shield.
3. Disconnect brake pedal return spring.
4. Remove locknut and eccentric bolt that connect return spring bracket and master cylinder push rod to brake panel bracket.
5. Remove snap ring from brake pedal pivot pin.
6. Remove outlet fitting bolt.
7. Remove cylinder mounting bolts and take off master cylinder.
8. Reverse removal procedure to install and bleed system of air.

STEERING GEAR

Adjustments

There are only two adjustments within this type steering gear, Fig. 4, and they should be made in the following order to avoid damage and gear failure.

1. Remove steering column floor pan cover.
2. Raise truck and disconnect drag link from steering gear.
3. Loosen steering gear-to-frame attaching bolts to relieve possible binding between steering column and worm shaft.
4. Loosen steering column-to-instrument panel bolts. Then re-tighten steering gear housing bolts.
5. From inside cab, loosen sector shaft adjusting screw lock nut and turn adjusting screw counterclockwise.
6. Remove horn button and spring and disconnect horn wire.
7. Measure worm bearing preload by attaching an inch-pound torque wrench to steering wheel nut. Read pull required to keep wheel moving for at least one complete turn. If torque is not within 3 to 6 inch-pounds, adjust as follows:
8. Loosen steering shaft bearing adjuster lock nut and tighten or back off bearing adjuster to bring preload within 3 to 6 inch-pounds. Tighten steering shaft bearing adjuster lock nut and recheck preload.
9. Turn steering wheel slowly and gently to either stop to avoid damage to ball return guides. Then rotate wheel approximately 2¼ turns to center ball nut.
10. Turn sector adjusting screw clockwise until it requires 8 to 13 inch-pounds to rotate worm past its center. *No perceptible backlash is permissible at 30° either side of center.*
11. Tighten sector adjusting screw lock nut and recheck backlash.
12. Tighten column bracket bolts, connect drag link, tighten instrument panel clamp bolts, install horn button and spring and connect horn wire.

Steering Gear, Replace

1. Disconnect horn and turn signal wires under instrument panel and free them from retaining clip.
2. Remove steering column floor pan.
3. Unfasten steering column clamp.
4. Disconnect transmission shift rods from shift tube arms.
5. Remove steering gear mounting bolts.
6. Remove bolt that clamps pitman arm to sector shaft. With a thin chisel spread pitman arm. Partially remove pitman arm from sector shaft, then move steering gear assembly from pitman arm.
7. Lift steering gear and column assembly out through passenger compartment.

Steering Gear Repairs

1. To disassemble, rotate steering shaft approximately 2¼ turns from either stop.
2. Remove sector shaft with cover.
3. Remove cover from shaft by turning screw clockwise. *Keep shim with screw.*
4. Remove adjuster and steering shaft upper bearing.
5. Pull steering shaft and ball nut from housing and remove steering shaft lower bearing. *Disassemble ball nut only if there is indication of binding.*
6. Remove bearing cups, seals or bushings only if damage is indicated.
7. With bearing adjuster in vise, remove upper and lower bearing cups.
8. Reverse disassembly procedure to reassemble, noting the following:
9. When assembling ball nut, count 31 balls and drop as many of them as possible into one of the guide holes, slowly turning worm away from hole until that circuit is full or until rotation is stopped by end of worm. If balls are stopped by end of worm, hold in those already positioned and

turn worm in opposite direction. Filling of circuit can then be continued until most of the balls are in place.

10. Lay one half of ball return guide on the bench and place the remainder of the 31 balls in it. Position second half of guide and, holding the two halves together, plug each open end with multi-purpose lubricant so balls will stay in guide when it is installed.
11. Push guide into guide holes of ball nut, tapping lightly with wooden handle of screwdriver if necessary.
12. Assemble second ball return circuit in same manner. Install guide clamp and check ball nut to see that it rotates freely.
13. Coat threads of steering shaft bearing adjuster, housing cover bolts and sector adjusting screw with oil-resisting sealing compound. *Do not apply sealer to female threads and especially avoid getting any sealer on steering shaft bearings.*
14. After installing steering wheel nut, adjust worm bearing preload as outlined above.
15. Position sector adjusting screw and shim and check end clearance which should not exceed .002" between screw head and end of sector shaft. If clearance is greater than .002", replace shim.
16. After loosely installing sector shaft adjusting screw lock nut, adjust sector shaft mesh (backlash) as outlined above.

fore, it does not function as an air pump.

This means that an external means of admitting air is provided. A specially designed blower on the side of the engine forces air into the cylinders to expel the exhaust gases and fill the cylinder with fresh air for combustion. Fig. 1 illustrates how this is done.

A systematic approach to tuning these engines should include the following steps, done in the sequence shown in Figs. 2 and 3.

VALVE LASH, ADJUST

The clearance between valve rocker arm and exhaust valve stem on two valve engines, and between valve rocker arm bridge and exhaust valve stem on four valve engines should be as listed in the *Specifications* chart when the engine is at operating temperature.

On two valve engines the clearance is set with a feeler gauge inserted between one valve stem and rocker arm; on four valve engines the feeler gauge is inserted between one valve stem and the bridge with the other end of the bridge resting on the other valve stem.

Maintenance of normal operating temperature is particularly important when adjusting the valve clearance. If the engine is allowed to cool off before setting any of the valves, the clearance when running at full load may become too small.

Insufficient valve clearance will result in loss of compression, misfiring of cylinders, and eventual burning of valves and valve inserts. Excessive clearance will result in noisy operation, especially in the low speed range.

If the rocker arm bracket bolts or cylinder head bolts are disturbed for any reason, the valve clearance should be adjusted to the cold setting (see Specifications) before starting the engine. Then, after the engine has reached operating temperature, recheck the valve clearance with engine running.

Two Valve Engines

1. With engine at normal operating temperature, place fuel shut down lever in the "no fuel" position.

Fig. 2 Tune up chart for engines with two exhaust valves per cylinder

DESCRIPTION

All GM diesel engines are of the same general type, differing only in the number of cylinders used. Service procedures for all these engines are the same except for slight details due to the additional number of cylinders. These differences will be considered by themselves wherever they occur.

All GM diesel engines are of the *two-stroke cycle type*. It is important to understand that this is not a four-stroke cycle engine and, therefore, differs considerably in its arrangements and operation.

In the conventional four-stroke cycle engine, four strokes are required to complete a cycle, and such engines function half the time as an air pump.

In the GM diesel engine, intake and exhaust takes place during part of the compression and power strokes, there-

Fig. 3 Tune up chart for engines with four exhaust valves per cylinder. Valve bridge adjustment applies to In Line 71 only

2. Rotate crankshaft until injector follower is fully depressed on the particular cylinder to be adjusted. *When using a wrench on the crankshaft bolt at the front of the engine, do not turn the engine in a left-hand direction as the crankshaft bolt will be loosened.*
3. Loosen push rod lock nut, Fig. 3A, and place the proper thickness feeler gauge between valve stem and rocker arm. Then adjust push rod to obtain a smooth "pull" on the feeler gauge.
4. Remove feeler gauge and while holding push rod, tighten lock nut.
5. Check and adjust remaining valves in the same manner.

Four Valve Engines

The procedure is the same as outlined for two valve engines except that the feeler gauge is inserted between the valve bridge and valve stem, Fig. 4. *Only one feeler gauge placed between one valve stem and the end of the rocker arm bridge is required to adjust the clearance. The other end of the bridge will rest on the other valve stem during adjustment. When the feeler gauge is removed, both valves will have their proper clearance.*

Service Note, 6-71 Four Valve Engines

Valve lash adjustment must always be made at the push rod. Do not disturb bridge adjusting screw. The exhaust valve bridge assembly is adjusted and the adjusting screw locked securely at the time the cylinder head is installed on the engine. Until wear occurs with operation of the engine, no further adjustment is required on the bridge. When wear is evident, a complete bridge adjustment must be made as follows:

1. Remove injector fuel jumper lines, then remove rocker arm shaft brackets. Lift rocker arms and swing

End cross section of a V-71 engine

Fig. 3A Adjusting valve lash on engines with two exhaust valves per cylinder

Fig. 4 Adjusting valve lash on engines with four exhaust valves per cylinder

End cross section of a Series 53 In-Line engine

Fig. 5 Adjusting valve bridge on 6-71 4-valve engines

them back to provide accessibility to valve bridge.

2. Remove bridge and spring from guide.
3. Place bridge in a vise and loosen adjusting screw lock nut.
4. Install bridge on bridge guide without spring.
5. Press straight down on pallet surface of bridge, Fig. 5. Turn adjusting screw until it just touches the valve stem, then turn screw an additional ⅛ to ¼ turn and tighten lock nut finger tight.
6. Remove bridge and fasten it in a vise. With screwdriver, hold screw from turning and tighten adjusting screw lock nut. Complete the operation by tightening lock nut to a torque of 25 lbs. ft., being sure that bridge does not turn. *Do not tighten while on engine as binding may damage bridge, guide and valve.*
7. Apply engine oil to bridge and bridge guide.
8. Reinstall bridge in its original position without bridge spring.
9. Place a .015″ feeler under each end of the bridge, Fig. 6. *Feeler used at inner end of bridge must be narrow enough to fit in bridge locating groove.* Pressing down on pallet surface of bridge, both feelers must be tight. If both feelers are not tight, readjust the screw as previously outlined.
10. Remove bridge and reinstall in its original position with bridge spring in place.
11. Adjust remaining bridges in same manner.
12. If cylinder head has been removed, reinstall on engine. Tighten cylinder head stud nuts to their specified torque before assembling rocker shaft brackets to head. This precaution is necessary to prevent valve damage due to mislocated bridges.
13. Install rocker arm assemblies, being sure valve bridges are properly positioned on the inner valve stems.
14. Tighten rocker shaft bracket bolts to a torque of 90-100 lb. ft.
15. Reconnect fuel jumper lines.

INJECTOR TIMING

To time the injectors properly, the injector follower must be adjusted to a definite height in relation to the injector body. All injectors can be timed during one full revolution of the crankshaft.

1. Place governor control lever in the *No Fuel* position.
2. Rotate crankshaft in the direction of engine rotation until the exhaust valves are fully depressed on the particular cylinder being timed. *Left-hand turning engines should not be turned in direction of rotation by use of wrench or crankshaft bolt.*
3. Place small end of injector timing gauge in hole provided in top of injector body with flat of gauge toward injector follower as shown in Fig. 7.
4. Loosen push rod lock nut.
5. Turn push rod and adjust injector rocker arm until the extended part of gauge will just pass over top of injector follower.

Fig. 6 Valve bridge adjustment check

6. Hold push rod and tighten lock nut. Check adjustment and readjust if necessary.
7. Time remaining injectors in like manner.

③—Maximum full load speed below 2000 RPM.

53 IN-LINE LIMITING SPEED GOVERNOR

Governor Gap, Adjust

1. With valve lash adjusted, fuel injectors timed, and engine at operating temperature, stop engine and proceed as follows:
2. Remove cover from speed adjusting screws, Fig. 8, and cover on top of governor.
3. Set idle adjusting screw to ⅜″ projection beyond lock nut, and tighten lock nut. *If desired, the idle adjusting screw may be correctly adjusted by starting the engine and setting the idle speed at 450 rpm.*
4. Start and run engine at 800 to 1000 rpm by manual operation of the control tube.
5. With engine operating as in Step 4, set the gap between the low speed spring cap and the high speed spring plunger at .0015″ by adjusting the gap adjusting screw in the operating shaft lever (bellcrank lever).
6. Hold gap adjusting screw and tighten lock nut. Recheck and readjust if necessary.
7. Install governor cover on its housing with the pin of the throttle control lever projecting into the slot of the differential lever and the cover screws tightened in the following manner:
   a. Install four cover screws and lockwashers finger tight.
   b. Pull cover assembly away from engine to take up slack around cover screws. This step is neces-

End cross section of a 6V-53 engine

Fig. 7 Timing fuel injector

Fig. 8 Adjusting governor gap. In-Line 53 engines

Fig. 9 Positioning No. 1 injector rack control lever. In-Line 53 engines

sary since no dowels project from governor housing to locate cover.

c. Tighten cover attaching screws while performing Step b.

Position Injector Control Racks

The position of the injector racks must be correctly set in relation to the governor. Their position determines the amount of fuel injected into each cylinder and ensures equal distribution of the load.

Adjust No. 1 injector rack control lever, Fig. 9, first to establish a guide for adjusting the remaining injector rack control levers.

1. Refer to Fig. 9 and disconnect any linkage attached to the throttle control lever.
2. Loosen lock nut and back out buffer screw approximately 5/8″ (see Fig. 13).
3. Loosen all inner and outer injector rack adjusting screws. Be sure all injector control levers are free on injector control tube.
4. Move throttle control lever to the FULL FUEL position as shown in Fig. 9. Turn inner adjusting screw down until a step up in effort is noted. This will place No. 1 injector rack in FULL FUEL position. Turn down outer adjusting screw until it bottoms lightly on the injector control tube. Then alternately tighten both the inner and outer adjusting screws until tight.
5. With governor control lever held in the FULL FUEL position, check for a slight movement of the injector control tube lever. This movement should not exceed .005″.
6. If no movement is observed, back off inner adjusting screw 1/8 of a turn and tighten outer adjusting screw. If the movement exceeds that specified, back off the outer adjusting screw 1/8 of a turn and tighten inner adjusting screw.
7. When the setting is correct, the injector rack will be snug on the pin of the rack control lever and still maintain the movement specified in Step 5.
8. Remove clevis pin between fuel rod and injector control tube lever. *Located under the control tube lever is a cylinder head oil drain back hole which should be covered when removing the fuel rod clevis pin to prevent its loss and possible damage to engine.*
9. Manually hold No. 1 injector in the FULL FUEL position and turn down inner rack control lever adjusting screw of No. 2 injector until the injector rack of No. 2 injector has moved into the FULL FUEL position and the inner adjusting screw is bottomed on the injector control tube. Turn outer adjusting screw down until it bottoms lightly on the injector control tube. Then alternately tighten both the inner and outer rack control lever adjusting screws until tight.
10. Recheck No. 1 injector fuel rack to be sure that it has remained snug on the pin of the rack control lever while adjusting No. 2 injector. If the rack of No. 1 injector has become loose, back off slightly on the inner adjusting screw on No. 2 injector rack control lever. Tighten outer adjusting screw. When the settings are correct, the racks of both injectors must be snug on the pin of their respective rack control levers.
11. Position the remaining rack control levers as outlined in Steps 9 and 10.
12. Insert the clevis pin between the fuel rod and injector control tube lever.
13. Reset idle speed adjusting screw until it projects 3/8″ beyond the lock nut. Tighten lock nut.

Maximum No-Load Engine Speed

All governors are properly adjusted before leaving the factory. However, if the governor has been reconditioned or replaced, and to ensure the engine speed will not exceed the recommended no-load speed given on the unit name plate, the maximum no-load speed may be set as follows:

Vehicle Units

1. Start engine and when it reaches operating temperature, remove load from engine.
2. Place engine throttle control lever in the Full Speed position and note engine speed.
3. Stop engine and, if necessary, refer to Fig. 10 and adjust engine to desired no-load speed as follows:
4. Remove high speed spring retainer, spring and plunger assembly, Fig. 11. *Be careful not to jar assembly while it is being removed to prevent the low speed spring and cap from dropping into governor.*
5. Remove high speed spring from its plunger and add or remove shims as required to establish the desired engine No-Load speed. Shims are available in .010″ and .078″ thickness. For each .010″ of shims added, engine speed will increase approximately 10 rpm.
6. Replace high speed spring on its plunger and assemble into governor housing. Install spring retainer in governor housing and tighten securely.
7. Start engine and recheck engine No-Load speed and readjust if necessary.

Industrial Units

1. Referring to Figs. 10 and 11, loosen lock nut and back off high speed spring retainer five turns.

Fig. 10 Differences between industrial and vehicle type governor spring assemblies. In-Line 53 engines

Fig. 11 Adjusting maximum no-load engine speed. In-Line 53 engines

Fig. 12 Adjusting engine idle speed. In-Line 53 engines

Fig. 13 Adjusting buffer screw. In-Line 53 engines

2. With engine at operating temperature and no load on the engine, place throttle control lever in FULL SPEED position. Turn high speed spring retainer IN until the engine is operating at the recommended no-load speed.
3. Hold retainer and tighten lock nut.

Idle Speed, Adjust

1. With maximum no-load speed properly adjusted, and with engine running at operating temperature and buffer screw backed out to avoid contact with differential lever, turn idle speed adjusting screw, Fig. 12, until engine idles at recommended idle speed. The recommended idle speed is 450 rpm for double weight limiting speed governors but may vary with special engine applications.
2. Hold idle speed adjusting screw and tighten lock nut.
3. Install high speed spring cover and retain with two bolts.

Buffer Screw, Adjust

1. With engine at idle speed, turn buffer screw IN so that it contacts differential lever as lightly as possible and still eliminates engine "roll", Fig. 13. *Do not increase engine idle speed more than 15 rpm with buffer*

Fig. 14 Limiting speed governor mounting. 6V-53 engines

Fig. 15 Checking governor gap. 6V-53 engines

screw.

2. Recheck maximum no-load speed. If it has increased more than 25 rpm from the top speed attained when previously adjusted, back off buffer screw until the increase is less than 25 rpm.
3. Hold buffer screw and tighten lock nut.

6V-53 LIMITING SPEED GOVERNOR

The limiting speed mechanical governor assembly is mounted near the rear of the engine, between the flywheel housing and the blower, Fig. 14. The governor is driven by the right blower rotor drive gear. The left blower rotor is driven by a shaft that passes through the governor housing from the engine gear train. There are two types of limiting speed governor assemblies. One type is generally used in industrial applications and the other is generally used in vehicles. The difference between each type will be pointed out later on.

After adjusting the exhaust valves and timing the fuel injectors as outlined previously, adjust engines with limiting speed governor as follows:

Governor Gap, Adjust

1. With engine at operating temperature, but not running, remove two bolts and withdraw governor high speed spring retainer cover.
2. Back out buffer screw until it extends ¾″ (see Fig. 20).
3. Start engine and loosen idle speed adjusting screw lock nut and adjust idle screw to obtain 450 rpm.
4. Stop engine and remove governor cover and engine rocker covers.
5. Start and run engine at 800 to 1000 rpm by manual operation of the differential lever, Fig. 15, and check governor gap between low speed spring cap and high speed spring plunger. Do not overspeed engine.
6. With engine operating at 800 to 1000 rpm, set gap between low speed spring cap and high speed spring plunger at .0015″ by adjusting the gap adjusting screw in the operating shaft lever (bellcrank lever).
7. Hold gap adjusting screw and tighten lock nut.
8. Recheck gap and adjust if necessary.
9. Stop engine and reinstall governor cover.

Position Injector Rack Control Levers

Adjust No. 3L injector rack control lever first to establish a guide for adjusting the remaining levers. The letters R or L indicate injector location in right or left cylinder bank, viewed from rear of engine. Cylinders are numbered starting at the front of the engine on each cylinder bank.

1. Disconnect any linkage attached to governor throttle control lever.
2. Adjust idle speed adjusting screw until ½″ of threads project from lock nut. *This adjustment lowers the tension of the low speed spring so that it can be compressed while closing the low speed gap without bending the fuel rods.*
3. Back out buffer adjusting screw ¾″, if not previously performed.
4. Remove valve rocker covers, if not previously done, and remove clevis pin between fuel rod and right cylinder bank injector rack control lever.
5. Loosen all inner and outer injector rack control lever adjusting screws on both cylinder banks. *Be sure all rack control levers are free on injector control tubes.*
6. Move throttle control lever, with light finger pressure, to FULL FUEL position. Turn inner adjusting screw of No. 3L injector rack control down, Fig. 16, until a step up in effort is noted. This will place No. 3L injector in FULL FUEL position. Turn down outer adjusting screw until it bottoms lightly on the injector control tube. Then alternately tighten both inner and outer adjusting screws. *Care should be taken to avoid setting rack too tight causing fuel rod to bend.*
7. With throttle control lever held in FULL FUEL position, check for a slight movement of the injector control tube lever toward the governor, Fig. 16. This movement should not exceed .005″.
8. If no movement is observed, back off inner adjusting screw ⅛ of a turn and tighten outer adjusting screw. If the movement exceeds that specified, back off the outer adjusting screw ⅛ of a turn and tighten inner adjusting screw. When the setting is correct, the injector rack will be snug on the ball end of the rack control lever and still maintain the movement specified in Step 7.
9. Remove clevis pin between fuel rod and left bank injector control tube lever.
10. Insert clevis pin between fuel rod and right cylinder bank injector control tube lever and position No. 3R injector rack control lever as previously outlined in Steps 6 through 9 for the No. 3L injector rack control lever.
11. Manually hold No. 3L injector rack in FULL FUEL position and turn down inner adjusting screw of the No. 2L injector rack control lever until the injector rack for No. 2L injector has moved to FULL FUEL position. Turn outer adjusting screw down until it bottoms lightly on injector control tube. Then alternately

Fig. 16 Adjusting No. 3L injector rack control lever. 6V-53 engines

Fig. 17 Adjusting maximum no-load speed. 6V-53 engines

tighten both inner and outer adjusting screws.

12. Recheck No. 3L injector rack to be sure that it has remained snug on the ball end of the rack control lever while positioning No. 2L injector rack. If the rack of No. 3L injector has become loose, back off slightly the inner adjusting screw on No. 2L injector rack control lever. Tighten outer adjusting screw. When the settings are correct, the racks of both injectors must be snug on the ball end of their respective rack control levers.
13. Position No. 1L injector rack control lever as outlined in Steps 11 and 12.
14. Position No. 2R and 1R injector racks as outlined above for the left cylinder bank in Steps 11 through 13.
15. Insert clevis pins between the fuel rods and injector control tube levers on both cylinder banks.
16. With the governor throttle control lever held in the FULL FUEL position, check for a slight movement of both right and left bank injector control tube levers. This movement should not exceed .005". Repeat above procedure if necessary.
17. Turn idle speed adjusting screw in until it projects 3/16" from the lock nut to permit starting of the engine.
18. Replace engine rocker covers.

Maximum No-Load Speed, Idle Speed & Buffer Screw Adjustments

These adjustments are made as outlined for the In-Line 53 engines. Refer to Figs. 17 to 20, and follow the procedure given for the In-Line engines.

V-71 LIMITING SPEED GOVERNOR

The two types of limiting speed mechanical governors used on V-71 engines are covered in this procedure. The difference between each type of governor is in the high speed spring retainer and spring housing assembly. Industrial engines usually use the governor without the dual range feature whereas on some vehicle applications it may be advantageous to use the dual range governor.

The only variation in the tune-up procedure between each type of governor is in the setting of the maximum no-load engine speed. Therefore, the setting of the maximum no-load engine speed is given for each type of governor under separate headings.

Adjust Governor Gap

1. With engine at operating temperature, and shut off, remove two bolts and withdraw governor high speed spring retainer cover.
2. Start engine and loosen idle speed adjusting screw lock nut and adjust idle speed screw to obtain 400 rpm.
3. Stop engine and remove governor cover and lever assembly.
4. Start and run engine at a speed between 800 and 1000 rpm by manual operation of the differential lever, Fig. 21. *Do not overspeed engine.*
5. With engine operating at 800-1000 rpm, set gap between low speed spring cap and the high speed spring plunger at .0015" by adjusting the gap adjusting screw in the operating shaft lever (bellcrank lever).
6. Hold gap adjusting screw and tighten lock nut.
7. Recheck gap and adjust if necessary.
8. Stop engine and reinstall governor cover and lever.

Position Injector Control Racks

The position of the injector control racks must be correctly set in relation to the governor. Their position determines the amount of fuel injected into each cylinder and ensures equal distribution of the load.

Adjust No. 1L rack control lever first to establish a guide for adjusting the remaining injector rack control levers. The letters R and L indicate injector location in right and left cylinder bank, viewed from rear of engine.

1. Disconnect any linkage attached to the governor throttle control lever.
2. Adjust idle speed adjusting screw until ½" of threads project from the lock nut.
3. Loosen buffer screw lock nut and back out screw approximately ⅝".
4. Remove valve rocker covers and clevis pin between fuel rod and right cylinder bank injector control lever.
5. Loosen all inner and outer injector rack control lever adjusting screws on both cylinder heads. Be sure all rack control levers are free on the injector control tubes.
6. Move governor cover throttle control lever to the "full fuel" position, holding in this position with light finger pressure. Turn the inner adjusting screw of No. 1L injector rack control lever down, Fig. 22, until a slight movement of the governor cover throttle control lever is observed, or a step-up in effort is noted. This will place No. 1L injector rack in "full fuel" position. Turn down outer adjusting screw until it bottoms lightly on the injector control tube. Then alternately tighten both inner and outer adjusting screws. *Care should be used to avoid setting rack too tight causing fuel rod to bend.*

Fig. 18 Differences between industrial and vehicle type limiting speed governors. 6V-53 engines

Fig. 19 Adjusting engine idle speed. 6V-53 engines

Fig. 20 Adjusting buffer screw. 6V-53 engines

Fig. 21 Adjusting governor gap. V-71 with limiting speed governor

7. With governor cover throttle control lever held in "full fuel" position, check for a slight movement of the injector control tube lever toward the governor. This movement should not exceed .005″.
8. If no movement is observed, back off inner adjusting screw approximately ⅛ turn and tighten outer adjusting screw. If movement exceeds .005″, back off outer adjusting screw approximately ⅛ turn and tighten inner adjusting screw. When the setting is correct, the injector rack will be snug on the ball end of the rack control lever and still maintain the .005″ movement.
9. Remove clevis pin between fuel rod and left bank injector control tube lever.
10. Manually hold No. 1L injector rack in "full fuel" position and turn down inner adjusting screw of No. 2L injector rack control lever until the injector rack of No. 2L injector has moved into the "full fuel" position. Turn outer adjusting screw down until it bottoms lightly on the injector control tube. Then alternately tighten both the inner and outer screws.
11. Recheck No. 1L injector rack to be sure that it has remained snug on the pin of the rack control lever while positioning No. 2L injector rack. If the rack of No. 1L has

Fig. 22 Positioning No. 1 injector rack lever. V-71 engine

Fig. 25 Adjusting maximum no-load speed. V-71 with limiting speed governor

become loose, back off slightly the inner adjusting screw on No. 2L injector rack control lever. Tighten outer adjusting screw. When the settings are correct, the racks of both injectors must be snug on the ball end of their respective rack control levers.

12. Position remaining injector rack control levers as outlined in Steps 10 and **11.**
13. Insert clevis pin between fuel rod and right cylinder bank injector control tube lever.
14. Position the right cylinder bank injector racks as outlined for the left cylinder bank in Steps 6 through 12.
15. Insert clevis pins between fuel rods and the injector control tube levers, both right and left cylinder banks.
16. With the governor throttle control lever held in "full fuel" position, check for a slight movement of both right and left bank injector control tube levers. This movement should not exceed .005", Fig. 22.

Fig. 23 Early dual range governor (top view). V-71 with limiting speed governor

17. Turn idle speed adjusting screw in until it projects $\frac{3}{16}$" from the lock nut to permit starting of the engine.

Adjust Maximum No-Load Engine Speed on Units Using Early Dual Range Governor

After positioning the injector control racks, with buffer screw backed out, set governor maximum speeds as follows:

With the spring housing assembly mounted on the governor and piston and sleeve assembled as shown in Fig. 23, and the low maximum speed adjusting screw extended from the spring housing approximately ¾" beyond the lock nut, proceed as follows: (To stop air leakage between piston and sleeve assembly coat the mating threads with a suitable sealer.)

1. Start engine and position engine throttle in maximum speed position.
2. Loosen lock nut and turn maximum speed adjusting screw inward until the desired no-load high maximum speed is obtained.
3. Stop engine and remove spring housing assembly. *Do not permit seal ring on piston to slide past air inlet port, since the seal ring will be damaged.*
4. Remove piston and sleeve from governor spring housing.
5. Turn piston on sleeve until piston is flush to $\frac{1}{64}$" below end of governor spring housing when piston and sleeve are placed in governor spring housing and held tight against adjustment screw of cover that is also positioned, with its gasket, against opposite end of spring housing.
6. Replace piston and sleeve in spring housing and assemble to governor.
7. Start engine and position throttle in maximum speed position and apply air pressure to governor. *To overcome tension of governor high speed spring, 50 psi air pressure will be required in governor spring housing.*
8. Back out low maximum speed adjustment screw ¼". If piston is adjusted correctly, engine will operate at recommended high maximum no-load speed set.
9. Remove air pressure from governor.
10. Make minor adjustment on piston and sleeve if necessary to establish exact speed desired.
11. To set low maximum no-load speed, adjust low maximum speed adjusting screw, with engine throttle control lever in the maximum speed position, until the desired low maximum speed is obtained. Turn screw inward to increase or out to decrease engine speed.

Fig. 24 Late dual range governor (top view). V-71 with limiting speed governor

Fig. 26 Adjusting engine idle speed. V-71 with limiting speed governor

Fig. 27 Adjusting buffer screw. V-71 with limiting speed governor

Fig. 28 Adjusting governor gap. In Line 71 with limiting speed governor

Fig. 29 Adjusting governor gap. In Line 71 with limiting speed governor

12. Tighten lock nut and recheck engine speed.
13. Check both high and low maximum engine speeds, and make any adjustment that is necessary.

Adjust Maximum No-Load Engine Speed on Units Using Newer Dual Range Governor

After positioning injector control racks and with the buffer screw backed out, set the governor maximum engine speeds as follows:

1. With the spring housing mounted on the governor and the piston and sleeve assembled with four .010″ shims and ten .010″ shims as shown in Fig. 24, and the low maximum speed screw extending approximately 1¼″ from spring housing, proceed as follows:
2. To set high maximum no-load speed, start engine and position throttle in maximum speed position.
3. Turn low maximum speed adjustment screw inward until the high maximum speed desired is obtained.
4. Stop engine and remove spring housing assembly. *Do not permit seal ring on piston to slide past air inlet port as the seal ring will be damaged.*
5. Note distance the piston is within the spring housing when it is against the low maximum speed screw, and then remove the sleeve from the piston.
6. Remove a quantity of shims that is equal to the distance the piston is from the end of the spring housing. The piston should be held tight against the adjustment screw of the

Fig. 30 Adjusting idle speed. In Line 71 with limiting speed governor

Fig. 31 Positioning injector control rack. In Line 71's

cover that is also held in position, with its gasket, against the opposite end of the spring housing.

7. Replace sleeve and piston and install spring housing onto governor.
8. Start engine and position throttle in the maximum speed position and apply air pressure to governor and note engine speed.
9. Remove air pressure from governor and stop engine. Then install or remove shims as required to obtain the correct high maximum no-load speed. Removing shims will decrease or adding shims will increase engine speeds. Each .010″ of shims removed or added will change engine speed approximately 10 rpm.
10. To set low maximum no-load speed, adjust low maximum speed screw with engine throttle control lever held in the maximum speed position until the desired low maximum speed is obtained. Turn screw in to increase or out to decrease engine speeds.
11. Recheck result and adjust as required.

Adjust Maximum No-Load Speed on Units Not Using Dual Range Governor

If the governor has been reconditioned or replaced, and to ensure the engine speed will not exceed the recommended no-load speed as given on the unit name plate, the maximum no-load speed may be set as follows:

1. Loosen spring retainer lock nut, Fig. 25, and back off high speed spring retainer approximately five turns.
2. With engine at operating temperature and no load on engine, place control lever in "full fuel" position. Turn high speed spring retainer in until engine is operating at recommended no-load speed.
3. Hold spring retainer and tighten lock nut.

Adjust Idle Speed

1. With engine running at normal operating temperature, and with buffer screw backed out to avoid contact with differential lever, turn idle speed adjusting screw until proper idle speed of 450-500 rpm is obtained. However, idle speed may vary with special engine applications, Fig. 26.
2. Hold idle screw and tighten lock nut.
3. Install spring retainer cover.

Adjust Buffer Screw

1. With engine running at normal operating temperature, turn buffer screw in so that it contacts the differential lever as light as possible and still eliminates engine roll, Fig. 27. *Do not increase idle speed more than 15 rpm with buffer screw.*
2. Hold buffer screw and tighten lock nut.
3. Recheck maximum no-load speed. If it has increased more than 25 rpm, back off buffer screw until increase is less than 25 rpm.

71 IN LINE LIMITING SPEED GOVERNOR

Adjust Governor Gap On Single Weight Units

1. With engine running at normal operating temperature, loosen idle speed adjusting screw lock nut, Fig. 28. Turn idle screw to obtain recommended idle speed, which is 550 rpm but may vary with special engine applications.
2. With engine stopped, remove governor cover.
3. Remove fuel rod, Fig. 29, between governor and injector control tube lever.
4. Using Tool J-5407, check gap between the low speed spring cap and high speed spring plunger.
5. If required, loosen lock nut and turn gap adjusting screw until a slight drag is felt on gauge.
6. Hold adjusting screw and tighten lock nut.
7. Recheck and adjust gap as necessary.
8. Install fuel rod and governor cover.

Adjust Governor Gap On Double Weight Units

1. With engine stopped after running it at operating temperature, remove cover from speed adjusting screws, Fig. 28, and cover on top of governor.
2. Set idle adjusting screw to ⅜″ projection beyond lock nut. Tighten lock nut.
3. Remove fuel rod from between governor differential lever to injector control tube lever, Fig. 28.
4. Start and run engine at 800-1000 rpm by manual operation of control tube. Do not overspeed engine.
5. With engine operating at 800-1000 rpm, set gap between low speed spring cap and high speed spring plunger at .0015″ by adjusting gap adjusting screw in operating shaft lever.
6. Hold adjusting screw and tighten lock nut.
7. Recheck and adjust gap if required.
8. Stop engine and install fuel rod and governor cover.

Position Injector Control Racks On Engines Using Fuel Modulator

When adjusting the fuel control racks be sure no interference is encountered from the fuel modulator. This may be assured by loosening the fuel modulator lever "U" bolt and moving the modulator lever along the injector control tube to avoid contact with modulator cam or adjacent cylinder head stud nut. When the modulator lever is in position, it may strike the cylinder head stud nut when the rack is moved toward the "off" posi-

Fig. 32 Governor-to-injector rack yield link

Fig. 33 Dual range limiting speed governor. In Line 71's

tion. The "no fuel" position is reached before this contact takes place and should therefore cause no concern.

1. Disconnect any linkage attached to governor control lever.
2. Loosen lock nut and back out buffer screw approximately 5/8", Fig. 30.
3. Loosen idle speed adjusting screw lock nut and back out idle screw until 9/16" of thread protrudes beyond lock nut.
4. Loosen all inner adjusting screws, Fig. 31. Be sure all control levers are free on injector control tube.
5. Move governor control lever to "full fuel" position. Turn inner adjusting screw down until a step up of effort is noted. This will place No. 1 injector rack in "full fuel" position. Turn down outer adjusting screw until it bottoms lightly on the injector control tube. Then alternately tighten inner and outer adjusting screws until tight.
6. Check setting of No. 1 injector rack by moving governor control lever toward "no fuel" position while holding governor-to-control tube link with light finger pressure, in a direction, toward the governor. This pressure will retain the low speed spring gap in the closed position when the throttle control lever is moved from the full speed position toward the idle position. A proper rack setting will be indicated by an immediate corresponding movement of the No. 1 injector rack from the "full fuel" position when the governor control lever is moved away from the "full speed" position.
7. If no immediate corresponding movement is observed, back off inner adjusting screw 1/8 of a turn and tighten outer adjusting screw. When setting is correct, the injector rack will be snug on the pin of the rack control lever and still maintain the movement mentioned in Step 6.
8. Remove clevis pin between fuel rod and injector control tube lever.
9. Manually hold No. 1 injector lever in "full fuel" position. Do not hold at end of control tube. Turn down inner adjusting screw of No. 2 injector until rack of No. 2 injector has moved into the "full fuel" position and the inner adjusting screw is bottomed on the injector control tube. Turn outer adjusting screw down until it bottoms lightly on injector control tube. Then alternately tighten inner and outer adjusting screws.
10. Recheck No. 1 injector fuel rack to be sure that it has remained snug on the pin of the rack control lever while adjusting No. 2 injector. If No. 1 rack has become loose, back off slightly on inner adjusting screw of No. 2 rack lever. Tighten outer adjusting screw. When settings are correct, the racks of both injectors must be snug on the pin of their respective rack control levers.
11. Position remaining rack control levers as outlined in Steps 9 and 10.
12. Insert clevis pin between fuel rod and injector control tube lever.
13. Reset idle speed adjusting screw, Fig. 30, until it projects 3/8" beyond lock nut and tighten lock nut.

Position Injector Control Racks On Units Without Fuel Modulator

1. Disconnect any linkage attached to control lever.
2. Loosen lock nut and back out buffer screw 5/8".
3. Loosen all control lever adjusting screws, being sure all control levers are free of the injector control tube.

NOTE—On some vehicle units a yield link is used between the governor and injector control rack, Fig. 32. It is necessary that a small "C" clamp be installed at the rod shoulder to provide a temporary solid rod. This is important since it prevents the possibility of compressing the yield link spring while setting the injector racks.

4. Move control lever to "full fuel" position. Turn inner adjusting screw down until a slight movement of the control tube is observed or a step up of effort is noted. This will place No. 1 injector rack in the "full fuel" position. Turn down outer adjusting screw until it bottoms lightly on the injector control tube. Then alternately tighten both the inner and outer adjusting screws.
5. With governor control lever held in "full fuel" position, check for a slight movement of the injector control tube lever. This movement should not exceed .005".
6. If no movement is observed, back off inner adjusting screw 1/8 of a turn and tighten outer adjusting screw. If movement exceeds .005", back off outer adjusting screw 1/8 of a turn and tighten inner adjusting screw. When the setting is correct, the injector rack will be snug on the pin of the rack control lever and still maintain the .005" movement.

Fig. 34 Adjusting maximum no-load speed. In Line 71's

7. Set the racks as outlined in Steps 8, 9 and 10 for units with the fuel modulator.
8. After completing the rack settings, remove the "C" clamp from fuel rod of units having a yield link, Fig. 32.

Adjust Maximum No-Load Speed On Dual Range Units

With injector racks set and buffer screw backed out, adjust as follows:

1. With governor assembled as shown in Fig. 33 and low maximum speed adjusting screw extending from the spring housing cover ¾" beyond the lock nut, start engine and position engine throttle in maximum speed position. To stop air leakage between piston and sleeve, coat mating threads with a suitable sealer.
2. Loosen lock nut and turn low maximum speed adjusting screw until desired no-load high maximum speed is obtained.
3. Stop engine and remove spring housing.
4. Remove piston and sleeve from spring housing.
5. Turn piston on sleeve until piston is flush to $\frac{1}{64}$" below end of spring housing when piston and sleeve are placed into spring housing and held tight against adjusting screw.
6. Replace piston and sleeve in spring housing and assemble to governor.
7. Start engine and position engine throttle in maximum speed position and apply air pressure to governor cylinder. To overcome the tension of the high speed spring, 50 psi air pressure will be required in the governor cylinder.
8. Back out adjustment screw ¼". If piston is adjusted correctly, the engine will operate at the recommended high maximum no-load speed set.
9. Remove air pressure from governor cylinder.
10. Make minor adjustment on piston to establish exact speed desired.
11. Adjust low maximum speed adjusting screw with engine operating and governor control lever held in "full fuel" position until desired speed is obtained. Turn screw inward to increase or outward to decrease engine speed. Tighten lock nut and recheck engine speed.

Adjust Maximum No-Load Speed On Units Without Dual Range Feature

If the governor has been reconditioned or replaced, and to ensure the engine speed will not exceed the recommended no-load speed as given on the unit name plate, adjust as follows:

1. Loosen lock nut and back off high speed spring retainer five turns, Fig. 34.
2. With engine at operating temperature and no load on the engine, place control lever in "full fuel" position. Turn high speed spring retainer in until engine is operating at recommended no-load speed.
3. Hold spring retainer and tighten lock nut.

Adjust Idle Speed

1. Refer to Fig. 33 and remove spring housing to uncover idle speed adjusting screw on dual range governors.
2. With engine running at normal operating temperature and with buffer screw backed out to avoid contact with differential lever, turn idle screw until the engine idles at recommended speed, Fig. 30. Recommended idle speed is 550 rpm for single weight limiting speed governors and 400 rpm for double weight limiting speed governors but may vary with special engine installations.
3. Hold idle screw and tighten lock nut.
4. Install spring housing cover and retain with two bolts.

Fig. 35 Fuel modulator adjustment In Line 71's

Adjust Buffer Screw

1. With maximum no-load and idle speeds properly adjusted, screw in buffer screw (with engine idling at operating temperature) so it contacts differential lever as lightly as possible and still eliminates engine roll. *Do not increase engine idle speed more than 15 rpm with buffer screw.*
2. On Series 71E and 71T engines, recheck maximum no-load speed. If it has increased more than 25 rpm from the top speed attained above, back off buffer screw until increase is less than 25 rpm.
3. Hold buffer screw and tighten lock nut.

Fuel Modulator, Adjust

A fuel modulator is installed in the cylinder head on turbocharged models, Fig. 35. This unit is controlled by air box pressure and operates in such a manner that the fuel injector racks are retarded as air box pressure drops due to reduced engine rpm. In addition, engine racks cannot move into full speed position until air box pressure is sufficient to provide proper combustion.

The following adjustments should only be performed after the other adjustments have been completed.

1. Hold fuel modulator piston and cam in high speed position by applying not less than 20 psi air pressure to piston or by prying cam out with a screwdriver, Fig. 35.
2. Hold injector rack in "Full Fuel" position. While holding injector rack, move fuel modulating lever and roller assembly until roller contacts cam; then carefully tighten clamping nuts on "U" bolt. Avoid changing position of roller while tightening clamp nuts.
3. Check adjustment several times as follows to be sure it is correct: Pry cam out with screwdriver. Move injector control tube to "Full Fuel" position. Relax pressure on screw-

IN LINE 71 FUEL MODULATING GOVERNOR

This unit, Fig. 36, was developed to improve combustion and fuel economy during low-speed full-throttle operation. This Fuel Modulator, incorporated with the mechanical limiting speed governor, automatically controls to fuel input to assure complete combustion, thus providing maximum fuel economy, clean exhaust and longer engine life. This control is assured regardless of the throttle setting maintained by the operator.

The governor includes a low speed spring a high speed spring, a set of low speed weights and a set of high speed weights.

In addition, the governor incorporating the fuel modulator includes a fuel modulator spring which provides governor control for the purpose of gradually reducing the fuel input in the fuel modulating range. Over this speed, the forces of the low speed and modulator springs react against the force of the high speed weights.

The fuel modulator spring tension is set so that the injector racks start to leave the "full in" position as engine speed is reduced. Engine speed at which this occurs is controlled by the weight and tension of the modulating spring used.

Fig. 37 charts the specified modulating and high speed spring combination to be used with each governor at the desired full load engine rpm.

Fuel Modulating Governors, R.P.M. and Springs

Governor Assembly	R.P.M.* Max.	R.P.M.* Min.	Modulator Spring	High Speed Spring
5113829	2300	1975	175# (G)	55# (Y)
5114156	2300	2075	225# (W)	55# (Y)
5183600	2300	2075	225# (W)	55# (Y)

*R.P.M. given is full-load; to obtain no-load (floor setting) speed, add 125 R.P.M.

When engine is equipped with rubber damper full-load speed must not exceed 2000 R.P.M. When full-load speed in excess of 2000 R.P.M. is desired, engine must be equipped with fluid (viscous) damper)

Color stripe -- (W) white, (G) green, (B) brown, (Y) yellow, and (R) red.

Fig. 37

Adjustments

Governor adjustments should not be performed until the valve lash is checked and adjusted and the injectors are properly timed.

The adjustments which follow should be made in the sequence given. Any deviation from this order may result in an improperly adjusted governor. Refer to Fig. 36 as a guide for the identification of parts.

Fuel Modulating Spring Tension

Preliminary Procedures—Remove covers (44 and 7), plug (9) and gasket. Disconnect governor external control linkage and remove cylinder head cover. Loosen lock nut (42) and back out idle screw (43) until low speed spring (59) exerts no pressure on low speed spring cap (61). This may be determined by moving cap in and out. Use care not to back the screw out too far as it is possible to turn it completely out of the low speed spring seat (58).

If the type of fuel modulating spring (55) is not known (70, 150, 175 or 225 lbs. per inch) the high speed plunger assembly should be removed from the governor, retainer ring (60) removed and the type of spring determined by color code, Fig. 37, before proceeding with following adjustment.

Loosen lock nut (37) and turn high speed adjusting screw (38) into body until flats on end of high speed spring plunger (39) are fully exposed.

Loosen lock nut (40) and turn modulating screw (41) out by hand until plunger (57) may be moved back toward high speed plunger $\frac{1}{16}$" before touching spring.

Adjustment—Turn screw (41) in by hand until resistance indicates that spring has forced plunger forward to contact retainer ring (60). Repeat as necessary until sure that plunger is just contacting ring with no tension on spring. Then turn screw (41) in a sixth of a turn (one flat). Lock adjustment with lock nut (40).

The plunger (39) and modulating spring adjusting screw (41) should both be held securely with two wrenches when tightening lock nut (40) to prevent screw and plunger relationship from being disturbed.

Low Speed Spring Gap Setting

Preliminary Procedures—Reset idle adjusting screw (43) to 2" projection ("A", Fig. 38) and replace control housing cover. *Be sure that throttle shaft pin is*

Fig. 38 Preliminary adjustment (3/4") of low and high speed springs

Fig. 39 Preliminary adjusting (3/8) of modulating cam

Fig. 40 Low speed spring gap adjustment

Fig. 41 Closing modulator gap with special screw

positioned between torsion spring (36) and end of differential lever (35).

Start engine and make preliminary idle speed setting at 385 rpm with low speed screw (43) and advancing speed to 400 rpm by turning in buffer screw (46). Tighten low speed lock nut (42) and stop engine.

Remove governor control housing cover and lever assembly (7). Remove gasket. Disconnect link rod between differential lever and injector control tube lever, then remove link through governor.

Thread buffer screw (46) outward 4 or 5 turns. Loosen cam adjusting screw lock nut (49). Remove plugging screw (51) and use Allen wrench to loosen cam lock screw (50) approximately 1/8 turn to permit cam to be moved in and out without allowing it to turn in housing.

Thread cam adjusting screw (48) into housing until screw extends 3/8" beyond lock nut when nut is against sleeve (Fig. 39). Tighten cam lock screw with Allen wrench to hold cam in position until adjusted later.

Start engine and operate between 600 and 700 rpm, using tachometer. Governor speed must be controlled by hand inasmuch as control linkage is disconnected.

Adjustment—Check gap between low speed spring cap (61) and modulating spring plunger (57) with .0015" feeler gauge (Fig. 40). If gap is not within .001-.002" at 600-700 rpm, loosen lock nut and turn adjusting screw as necessary to obtain proper gap. Tighten lock nut and recheck gap.

Fuel Modulating Gap Closing

Preliminary Procedures—Install control link between differential lever and injector control tube lever, being sure link is not binding.

Start engine and control speed manually by exerting force against torsion spring (36) with finger.

Adjustment — Advance engine speed gradually until low speed spring cap (61) contacts high speed plunger (38). Do not exceed 2100 rpm. Gap closing speed should be checked with a .0015" feeler between mating surfaces of (61) and (38). The speed will vary according to the following table:

Spring Color	Closing Speed
White	1950-2040
Green	1850-1940
Brown	1750-1840
Yellow	1525-1625

If closing speed does not fall in the correct range, recheck the preceding adjustments. If the preceding adjustments are correct and the closing speed still does not fall within the proper range, a new modulating spring should be installed.

Fuel Modulating Cam Setting

Preliminary Procedures—With engine stopped, set high speed adjusting screw so it extends 3/4" beyond its lock nut when nut is tight against housing (Fig. 38).

Temporarily install cap screw (1/2-13x2") into front of control housing and thread screw inward until gap between low speed cap and high speed spring plunger just closes, Fig. 41, being careful that plunger is not moved.

Fig. 42 Modulating cam adjustment

Fig. 43 Adjusting No. 1 rack to fuel modulating governor

Fig. 44 Adjusting No. 2 rack to No. 1 rack

Fig. 45 High Speed Adjustment

Loosen inner and outer adjusting screws at each control rack lever until each lever is free on control tube. Install governor control housing gasket and cover, being sure that throttle shaft pin is between differential lever (35) and torsion spring (36).

Adjustment—Loosen cam lock screw (50) with Allen wrench 1/8" turn to permit turning cam adjusting screw (48) with fingers. If lock screw is backed out further, cam may be released by its own weight out of the operating position.

With control lever in full throttle position, Fig. 42, thread cam adjusting screw outward with finger tips until cam can be felt bottoming against roller (34) on the bottom of the differential lever (35). Thread cam adjusting screw outward an additional 1/8 turn to provide positive engagement between differential lever roller and cam. After making contact it may be necessary to turn the screw very slightly in or out to produce the final 1/64" clearance illustrated in Fig. 42, which is required after the Allen screw has been tightened.

Injector Rack Setting

1. Manually hold control lever in full throttle position, Fig. 43.
2. Adjust No. 1 injector rack lever, Fig. 43, so that very light finger tip pressure at the coupling *will produce a tendency to roll, but coupling should not be loose.*
3. Hold injector control tube for "feel" while adjusting remaining control rack couplings, Fig. 44.
4. Adjust No. 2 rack control lever so that it has the same "feel" as No. 1 coupling.
5. Repeat this procedure on all remaining racks. That is, compare No. 3 with No. 1 etc., making sure no other injector is tighter than No. 1.

No Load High Speed Setting

1. Remove the temporarily installed cap screw and install the control housing plug and gasket.
2. Loosen high speed adjusting screw lock nut if tight.
3. Install cylinder head cover.
4. Start engine and move throttle lever toward full fuel position while observing tachometer. Avoid overspeeding engine more than 100 rpm above desired speed.
5. Turn high speed adjusting screw (39) until desired speed is obtained with throttle lever in wide open position, Fig. 45, and tighten lock nut.

Idle Speed and Buffer Screw Setting

1. With engine running at idle speed, observe engine rpm on tachometer. Then loosen lock nut (42) and thread idle adjusting screw (43) in to increase or out to decrease until 385 rpm is obtained. Tighten lock nut.
2. With engine running at idle speed, thread buffer screw (46) in until "surge" or "roll" of engine just disappears, but not higher than 400 rpm. Variation from this speed will affect fuel modulating action.
3. Do no raise engine more than 20 rpm with the buffer screw, otherwise it may not be possible to stop the engine. Hold screw (46) and tighten lock nut. Start and stop engine several times to be sure of its stopping.

Trouble Shooting

Hard Starting

1. Throttle not in starting position.
2. Emergency shut-off valve at blower is partially or completely closed.
3. Fuel tank empty, fuel filter empty, or fuel pump not primed.
4. Improper injector timing or rack setting.
5. Insufficient fuel or faulty fuel pump.
6. Improper grade and type of fuel.
7. Improperly filtered fuel.
8. Fuel diluted with water.
9. Air in fuel supply system.
10. Low compression due to valves in poor condition, improper valve lash, worn or scored pistons or liners.
11. Defective blower.
12. Defective injector.

Uneven Running & Excessive Vibration

1. Faulty injector timing or rack setting.
2. Fuel supply insufficient.
3. Governor adjustment.
4. Coolant temperature too low. Inspect and test thermostat in water manifold and in shutter.
5. Valves in poor condition. Check compression pressure as outlined at the end of this section.

One or More Cylinders Cut Out

1. Remove valve cover.
2. Run engine at idle speed.
3. Check valve lash on all cylinders with engine hot—should be .009"
4. Operate engine at 600-800 rpm.
5. Cut out each cylinder in turn. Injector is cut out by holding follower down with screwdriver. If a decrease in speed is noted, it indicates that the injector is working. If no increase in speed is noted, the injector is not functioning.
6. Stop engine and remove fuel line from injector to return manifold.
7. Hold finger over injector fuel outlet and crank engine with starter. A gush of fuel at injector while starter is turning engine indicates ample fuel supply.
8. Remove injector and replace with a new one. If no spare injector is at hand, repair or clean injector and spray tip.
9. If the new or repaired injector has not eliminated the condition, the compression pressure of the cylinder in question should be checked.

Air In Fuel System

1. Disconnect fuel return line and run engine. Observe if air bubbles are discharged with fuel. This can best be done by submerging the end of the pipe in an open can of fuel.
2. Remove one fuel pipe to injector at end of engine which is highest (if standing on uneven ground) and install combination sight glass and pressure gauge fixture. Air bubbles will show up in sight glass.
3. If air is present, inspect all fuel line connections from suction side of fuel pump to the fuel tank. Inspect for cracked tubing flared ends; primary filter gasket; holes chafed through fuel suction line; cracks arising from screwing fittings in too tight at fuel pump and filter.

Engine Stalls Frequently

1. Idling speed too low.
2. Coolant temperature too low.
3. One or more cylinders cutting out.
4. Governor surging. Remove all bind from injector control rack operating shaft mechanism.
5. Clogged fuel oil filters.
6. Unsatisfactory injectors.
7. Improper governor adjustment.
8. Governor linkage incorrectly set.
9. Air in fuel system.

Loss of Power

1. Injector racks improperly positioned.
2. Faulty injector timing.
3. One or more cylinders cutting out.
4. Air cleaners choked.
5. Insufficient fuel supply.
6. Choked fuel filter.
7. Air in fuel system.
8. Unsatisfactory injectors.
9. Improper governor adjustment.
10. Loss of compression.
11. Fuel tank air vent plugged.
12. Governor low-speed spring gap improperly adjusted.

Black Smoke In Exhaust

1. Poor grade of fuel.
2. Injector timing late.
3. Unsatisfactory injector.
4. Inlet air restriction too high.

Blue Smoke In Exhaust

1. Injector racks not properly positioned.
2. Cylinder cutting out.
3. Lubricating oil entering combustion chambers: (a) Piston rings worn or stuck, oil rings assembled incorrectly. (b) Oil leaks into air box or blower housing due to leaky gasket or blower rotor shaft seals. (c) Oil level too high in air cleaners.
4. Engine temperature too low.

Engine Detonates

If a hard metallic knock indicates detonation in one or more cylinders, the engine must be stopped immediately to prevent serious damage due to excessive pressure accompanying detonation. Detonation is caused by the presence of fuel

or lubricating oil in the air charge of the cylinders during the compression stroke. The engine should be checked for:

1. Leaky injectors. Locate bad cylinder by cutting out injectors one at a time.
2. Leaking fuel connections in cylinder head.
3. Crankcase dilution due to fuel leaks. Drain and refill crankcase with specified oil. Inspect air box and blower and clean out with compressed air. Inspect piston rings.
4. Oil pull-over from air cleaners.
5. Leaky blower housing gasket.
6. Leaky blower oil seals.
7. Plugged air box drains.

Lack of Lube Oil Pressure

1. Oil supply in crankcase low, allowing pump to suck air.
2. Crankcase oil diluted by fuel oil. Observe odor of oil from crankcase for traces of fuel. Check for fuel oil leaks.
3. Use of improper lube oil.
4. Worn main or rod bearings.
5. Oil pressure relief valve sticking.
6. Oil cooler plugged.
7. Oil pump screen plugged.
8. Oil pump drive inoperative.
9. Oil lines choked, improperly tightened or ruptured gaskets.

Engine Runs Unevenly or Stops Frequently

These conditions are caused by water in fuel or low fuel pressure. Water in fuel necessitates draining fuel tanks and filling with clean fuel oil. Disconnect fuel line and allow engine to run and discharge fuel into a container until fuel system is purged.

Checking Compression Pressure

1. Remove valve rocker cover.
2. Start on No. 1 cylinder and remove fuel lines from both injector and fuel connectors.
3. Remove injector from No. 1 cylinder and install a 1000-lb. compression gauge in its place.
4. Use one of the fuel lines as a jumper connection between the fuel inlet and return manifold connectors. This will permit fuel from the inlet manifold to flow directly to the return manifold.
5. Run engine at approximately 500 rpm and take readings on the gauge. Do not take compression pressure by cranking engine with starter.
6. Perform this same operation on each cylinder in turn. The compression pressure on any one cylinder should not drop below 385 lbs., nor should the pressure for any one cylinder be more than 25 lbs. below the reading on the others.

Blower & Turbocharger Section

DESCRIPTION

The blower supplies fresh air required for combustion and scavenging. Its operation is similar to that of a gear type oil pump. Two rotors revolve in a housing bolted to the engine. The revolving motion of the rotors provides a continuous and uniform displacement of air.

On Series 53 In-Line and 6V-53 engines, two hollow double lobe rotors are used. On Series 71 and V-71 engines, the two rotors have three lobes and are made in a twisted or helical form. On 12-cylinder engines, two 6V blowers, coupled together by means of a chain and sprocket, are mounted in tandem on the top deck of the engine.

The blower rotors are timed by the two gears at one end of the rotor shafts. This timing must be correct otherwise the required clearance between rotor lobes, obtained by the use of shims behind the gears, will not be maintained.

Fig. 1 Disassembled view of Series 53 four cylinder engine blower

BLOWER INSPECTION

A blower with a removable air inlet housing may be inspected for any of the following conditions without being removed from the engine. However, the air filter and air inlet housing or air silencer must be removed from the blower.

CAUTION: When inspecting a blower on the engine with the engine running, keep fingers and clothing away from moving parts of the blower and run engine at low speeds only.

1. Dirt or chips, drawn through the blower, will make deep scratches in the rotor and housing and throw up burrs around such abrasions. If burrs cause interference between rotors or between rotors and housing, the blower should be removed from the engine and parts dressed down to eliminate interference, or the rotors should be replaced if they are badly scored.
2. Leaky oil seals are usually indicated by the presence of oil on the blower rotors or inside surfaces of housing. This condition may be checked by running the engine at low speed and directing a light into the rotor compartment at the end plates and the oil seals. A thin film of oil radiating away from the seal is indicative of an oil leak.
3. Worn blower drive resulting in a loose, rattling sound within the blower may be detected with the engine operating at idling speed. If a worn blower is suspected, the blower must be removed from the engine before repairs can be effected.
4. Loose rotor shafts or worn rotor shaft bearing surfaces will result in contact between rotor lobes, rotors and end plates, or rotors and housing.
5. Excessive backlash in blower timing gears usually results in rotor lobes rubbing throughout their entire length.

Fig. 3 Disassembled view of blower for In-Line 71 engines

BLOWER REPLACE

4-53 In-Line Engine

Fig. 1 shows a disassembled view of the blower used with these engines. To remove the blower, proceed as follows:

1. Remove air cleaner or any ducting.
2. Disconnect Bowden wire from air shut-off cam pin handle.
3. Unfasten air inlet housing from blower and remove housing from blower.
4. Loosen clamp retaining cover to drive support seal.
5. Unfasten blower from engine (4 bolts) and lift blower away from engine, being careful not to damage serrations in blower drive shaft.

Installation

1. Before attaching blower to engine, examine inside of blower for any foreign material and revolve rotors by hand to be sure they turn smoothly. Rough particles in the blower may score the rotors and impair blower efficiency.
2. Install a new blower-to-block gasket at blower mounting pad on engine. Use a non-hardening gasket cement on block side only.
3. Slide seal with clamp over end of blower drive shaft cover portion of rear end plate cover. Loosen blower drive support bolts prior to mounting blower to block.
4. Place blower on block locating flanges and slide assembly into position. Be careful not to damage gasket at blower mounting pad. Be sure that splines in blower drive shaft mesh with splines in cam in blower drive spring assembly.
5. Install blower-to-block mounting bolts and washers and torque to 46-50 ft. lbs.
6. Slide seal and clamp back against blower drive gear support and tighten clamp. Torque drive gear support bolts to 35 ft. lbs.
7. At this time, check backlash between blower drive gear and camshaft or balance shaft gear; should be .003″ to .005″ with new parts.
8. Install air inlet housing and air cleaner.

Fig. 2 Removing governor drive support. 6V-53 engine

6V-53 Engines

The blower and governor are bolted together and must be removed as an assembly, the procedure for which is as follows:

1. Disconnect linkage to governor control levers.
2. Remove cover from governor housing.

Fig. 4 Disassembled view of blower for V-71 engines

3. Remove spring housing from governor housing.
4. Remove spring assembly from governor.
5. Loosen hose clamps and slide hoses back on fuel rod covers.
6. Remove rocker cover from each cylinder head.
7. Disconnect lower fuel rod from each injector control tube lever and also from each upper fuel rod to governor.
8. Remove threaded pins connecting fuel rods to control link lever.
9. Remove upper fuel rods.
10. Remove blower drive cover plate. Remove retainer ring and withdraw blower drive shaft out of housing.
11. Remove governor drive support, Fig. 2.
12. Unfasten and remove blower and governor (4 bolts) from engine. Note that governor is doweled to rear end plate.
13. Unfasten governor housing (6 bolts) from blower rear end plate and remove governor housing and gasket.

Installation

1. Secure governor to blower rear end plate.
2. Install O-ring seal and two fiber gaskets on face of block between cylinder banks.
3. Lower blower and governor assembly onto engine. *The governor is doweled to the rear end plate, and the governor end of the blower must be placed in position before the blower can be lowered into position.*
4. Install blower mounting bolts and torque to 10-15 ft. lbs.
5. Attach a new gasket to blower drive support. On limiting speed governors, position the light (high speed) weights in a horizontal position to provide clearance, Fig. 2.
6. Move blower drive assembly straight in towards openings in flywheel housing until blower drive gear enters housing. The drive assembly must be turned slightly so that serrated end of governor weight shaft may pass around governor operating fork, permitting fork to slide into position between serrated end of shaft and the riser bearing. Push drive support up against flywheel housing. *Serrations in governor weight shaft and governor drive plate on timing gear must mesh. Also, blower drive gear must mesh with mating camshaft gear.*
7. Secure governor drive support to flywheel housing and torque bolts to 20-25 ft. lbs.
8. Insert blower drive shaft through blower drive gear hub. *It may be necessary to turn the crankshaft slightly so that serrations on each end of blower drive shaft will register with serrations in flexible coupling on blower timing gear and in blower drive hub.*
9. Install snap ring to secure blower drive shaft.
10. Install blower drive support cover with new gasket and torque bolts to 20-25 ft. lbs.
11. Tighten blower-to-block bolts to 45-50 ft. lbs.
12. Insert upper fuel rods through fuel rod covers, hoses and clamps and attach fuel rods to governor control link lever with link pins threaded into lever.
13. Attach lower fuel rods to injector control tube levers and upper fuel rods.
14. Slide fuel rod cover hoses in place and secure with clamps.
15. Install spring assembly as follows:
    a. Thread spring retainer lock nut onto retainer.
    b. Thread idle adjusting screw into governor spring plunger.
    c. Place high speed spring over governor spring plunger.
    d. Lubricate and install spring and plunger in retainer and secure with lock nut so that ¼″ of idle adjusting screw extends beyond nut.
    e. Lubricate and insert spring seat, low speed spring, and spring cap in open end of spring plunger.

Series 71 In-Line Engines

Fig. 3 shows a disassembled view of the type blower used with these engines. In most cases, removal of the blower, together with governor drive, water pump, fuel oil pump and blower drive shaft cover will be found advantageous.

1. Drain water from cooling system.
2. Remove governor.
3. Disconnect fuel lines at fuel pump.
4. Loosen water pump connections at pump cover and cylinder block.

Fig. 5 Single blower mounting for V-71 engine

Fig. 6 Tandem blower mounting for V-71 engine

5. Remove air cleaner or silencer, blower inlet screen, and any breather pipes.
6. If unit is equipped with a turbocharger, disconnect any inlet and outlet water and oil lines from turbocharger. Loosen clamps and slide hose and clamps back on air inlet housing or turbocharger outlet tube.
7. Disconnect any other lines attached to blower, blower inlet housing or turbocharger.
8. If engine is equipped with automatic overspeed trip, remove and tag wires from overspeed governor and from overspeed trip solenoid.
9. Remove blower drive cover with overspeed governor attached.
10. Remove blower drive shaft.
11. If engine is equipped with hand control overspeed trip, disconnect Bowden wire control at valve shaft lever located at lower rear corner of air inlet housing.
12. Loosen clamp on blower drive shaft cover seal.
13. Remove mounting bolts at top and bottom of blower housing.
14. Slide blower assembly (including accessories) slightly toward forward end of cylinder block to withdraw blower drive shaft cover from seal, then pull blower away from cylinder block.

Installation: With fuel pump, blower drive shaft cover, water pump and governor drive housing assembled to blower, mount blower to engine as follows:

1. Before attaching to engine, examine inside of blower for any foreign material and revolve rotors by hand, checking for smooth turning.
2. Affix a gasket to cylinder block at blower mounting boss, using a non-hardening gasket cement on block side only.

Fig. 7 Method of coupling tandem blowers together. V-71 engines

Fig. 8 Blower rotor clearances. Series 53 and 6V-53 engines

3. Slide a new seal with clamp over end of blower drive shaft cover.
4. Slip water pump outlet packing flange (flat face out) and new packing over pump outlet.
5. Avoid damage to gasket at blower mounting boss on cylinder block and slide blower into position.
6. Attach blower to block and torque bolts to 55-60 ft. lbs.
7. Slide seal and clamp back against blower drive gear support and tighten clamp.
8. Install blower drive shaft by pushing plain end (end without square hole) on shaft through blower drive coupling from rear of engine, thence into blower drive gear hub. It may be necessary to revolve rotors slightly to engage splines of drive shaft with those of gear hub.
9. When using "short" blower drive shaft, install lock ring in blower drive cam.
10. If equipped with an automatic overspeed trip, install blower drive cover and overspeed trip governor and attach wires to governor.
11. Install air inlet housing together with screen, striker plate and other parts located between inlet housing and blower. Also, install overspeed trip solenoid and attach wires to solenoid.
12. If equipped with hand control overspeed trip, connect Bowden wire control at valve shaft lever located at lower rear corner of blower air inlet housing.
13. Tighten bolts securing blower drive shaft cover to end plate cover.
14. Connect water pump outlet packing flange to cylinder block.
15. Install air cleaners, silencer or any breather pipes in air system.
16. Connect fuel lines to fuel pump.
17. Connect any water and oil lines from turbocharger (if equipped).
18. Connect any other lines attached to blower, inlet housing or turbocharger.
19. When filling cooling system, open vent valve at top of thermostat housing if so equipped.

V-71 Engines

Fig. 4 shows a disassembled view of a blower used on these engines, while Figs. 5 and 6 illustrate a single blower and a tandem blower mounting, respectively.

The engine governor components are assembled in a combination governor housing and blower front end plate cover. The fuel pump is also attached to the front end of the blower. Therefore, when removing the blower from the engine, the governor and fuel pump will also be removed at the same time.

1. Unfasten and remove air inlet housing from air shut-down housing.
2. Disconnect Bowden wire from air shut-down cam pin handle.
3. Remove shut-down housing (6 bolts).
4. Remove bolts which attach air inlet or air silencer adaptor to blower and remove adaptor and blower screen.
5. Loosen oil pressure line fitting from rear of blower-to-blower drive support.

MAX.				.006"		

NOTE: Time rotors to dimensions on above chart for clearance between trailing side of R.H. Helix Rotor and leading side of L.H. Helix Rotor (cc) from both inlet and outlet side of blower.

Fig. 10 Chart of minimum blower clearances for V-71 engines

6. Loosen hose clamp on blower drive support-to-blower seal.
7. On units with tandem blowers, loosen clamp securing seal between front and rear blowers.
8. Disconnect tachometer drive cable from adapter at rear of blower (if equipped).
9. Remove flywheel housing cover at blower drive support.
10. Remove snap ring and withdraw blower drive shaft from blower.
11. Loosen hose clamps and slide hoses back on by-pass tube between thermostat housings. Remove by-pass tube.
12. Remove fuel inlet and outlet lines to fuel pump. Also, remove fuel return cross-over tube between cylinder heads.
13. Remove or disconnect breather pipe at top of cylinder block.
14. Remove front engine lifter bracket if necessary.
15. Disconnect throttle control rods from governor.
16. Remove rocker cover from each cylinder head.
17. Remove governor cover (8 screws).
18. Remove fuel rods from both injector rack control tube levers.
19. Loosen hose clamps and slide governor fuel rod cover back on each side of governor.
20. Remove bolt through top of each end plate which secures blower to cylinder block.
21. Remove blower-to-block bolts, retaining lugs and washers on each side of blower.

Fig. 11 Chart of minimum blower clearances for Series 71E and 71T engines

Fig. 12 Showing proper location of shims for correct rotor lobe clearances on Series 71 In-Line engines

22. Check to make sure any other tubing or accessories are disconnected which may interfere with removal of blower.
23. Thread eyebolts in diagonally opposite air inlet adaptor-to-blower tapped holes and attach a sling to a hoist.
24. Lift blower slightly and move forward to detach blower from seal at drive end. Then lift blower up and away from engine. *On units equipped with tandem blowers, the front blower must be removed first. Move front blower slightly forward to disengage drive chain from sprockets, then lift blower away from engine. Move rear blower forward to detach seal at rear of blower, then lift rear blower away from engine.*

Fig. 13 Showing proper location of shim for correct rotor lobe clearances. V-71 engines

Installation: After end plate covers and accessories are installed on blower, refer to Figs. 5, 6 and 7 and install blower on engine.

First place a new blower gasket on top of cylinder block, using non-hardening cement to prevent gasket from shifting. Then lower blower in position and reassemble to engine by reversing the procedure used for removal.

Secure blower to cylinder block with bolts, retaining lugs and washers and torque bolts uniformly to 25 ft-lb in 5 ft-lb increments.

On tandem installations, install rear blower first. Position drive chain, blower seal and clamp on rear blower, then lower front blower in place. Make sure drive chain is in position on both the drive and driven sprockets, then slide seal into position and secure clamp.

TIME BLOWER ROTORS

Series 53 & 6V-53 Engines

If the blower has been disassembled, after it has been reassembled, the rotors must be timed. The rotors, when properly positioned, run with a slight clearance between rotor lobes and with a slight clearance between the lobes and housing walls. The necessary clearances may be established by moving one of the gears out or in on the shaft relative to the other gear. Moving the gears out or in on the rotors is accomplished by adding or removing shims between the gear hub and rotor spacers.

It is preferable to measure the clearances with a feeler gauge comprised of two or more feelers since a combination is more flexible than a single feeler gauge. Measurements should be taken from both the inlet and outlet sides of the blower.

The clearance between rotor lobes and housing is measured as shown in Fig. 8. Measurements should be taken across the entire length of each rotor lobe to be certain that a maximum clearance of .004" exists at the air outlet side of all blowers. A minimum clearance of .0075" should exist at the air inlet side of the In-Line engine blowers and .010" minimum for V-type engine blower. Similarly, the clearance between rotor lobes should be measured across the length of the lobes.

By rotating the gears, position the lobes so that they are at their closest relative position as shown in Fig. 8. The clearance between the lobes should be .010".

The clearance between the ends of the rotors and blower end plates should be .008" minimum at both end plates.

Series 71 & V-71 Engines

The rotors, when properly positioned in the housing, run with a slight clearance between the lobes, Figs. 9, 10, 11. This clearance may be varied by moving one of the helical gears in or out on the shaft relative to the other gear.

If the upper gear is moved out, the upper rotor will turn counterclockwise when viewed from the gear end. If the lower gear is moved out, the lower rotor will turn clockwise when viewed from the gear end.

Moving the gears in or out on the rotors is accomplished by adding or removing shims between the gear hub and the bearing back of the gears. Three .002" shims are required to revolve rotor .002".

Having determined the amount one rotor must be revolved to produce the proper clearance, observe the engine model on which the blower is to be used and add shims as required to produce the desired result, Figs. 12, 13.

TURBOCHARGER

A turbocharger is designed to increase the power output and improve the efficiency of an engine. Power to drive the turbocharger is extracted from waste energy in the engine exhaust gas.

The unit consists of a radial flow turbine, a centrifugal compressor, a bearing carrier which serves to support the rotating assembly, a main housing, a turbine housing and a compressor housing.

In operation, all exhaust gases from the engine pass through the turbine end of the assembly before they are discharged into the atmosphere. After the engine is started, the flow of exhaust gases will begin operating the turbocharger. During operation, the turbocharger responds to the engine load demands by reacting to the flow of exhaust gases and the corresponding air demand of the engine. Fig. 14. A cutaway view of a Turbocharger is illustrated in Fig. 15.

The compressor impeller is directly connected to the turbine which is driven by the engine exhaust gases. These hot exhaust gases expand through the turbine nozzle, and the turbine wheel, thus producing torque and power to drive the compressor. Intake air enters the compressor housing, flows through the impeller, is compressed and supplied to the inlet manifold of the engine.

The turbocharger responds to engine load demands without any control connections between engine and turbocharger. Regulation of the turbocharger is automatic, and is accomplished without any special couplings, gears or valves.

There are several model turbochargers available, each designed for a particular engine. The serial and model numbers

Fig. 14 Schematic flow diagram of a Turbocharger

Fig. 15 Cutaway view of a Turbocharger

and size of the turbocharger are stamped on the name plate attached to the blower housing.

Inspection

Performance of the turbocharger should be observed at reasonable intervals for the following conditions:

Engine lubricating oil pressure should be kept at about 30 to 40 psi at the turbocharger speed corresponding to full engine load. The lubricating oil pressure gauge should be observed each time the engine is started or shut down. Particular attention should be paid to keeping the lubricating oil clean by regular changing and renewing of the engine filter elements.

Turbocharger cooling water temperatures should be checked occasionally to make sure that the temperature rise across the turbocharger does not exceed 30 degrees F. A high temperature rise across the unit indicates stoppage or plugging of the coolant passages.

Operation of the unit should be observed frequently to detect any noticeable vibration. If noticeable vibration develops, the unit should be stopped and the cause determined. Vibration might be caused by damage to the impeller, shaft or turbine wheel, or by worn or loose bearings in the unit.

Fuel Injector & Fuel Pump Section

DESCRIPTION

The cross section of the fuel injector, Fig. 1, shows the various fuel injector parts. Fuel oil supplied to the injector enters the body at the top through the filter cap. After passing through the filter element in the inlet passage, the fuel oil fills the supply chamber between the bushing and the spill deflector. The plunger operates up and down in this bushing, the bore of which is connected to the fuel supply by two funnel-shaped ports.

Motion of the injector rocker arm, Figs. 2, 3, is transmitted to the plunger by the follower which bears against the plunger. The follower, follower guide, and plunger are held together as an assembly by a straight pin. The follower assembly is positioned in the body by a follower stop pin.

In addition to up and down motion, the plunger can be rotated around its axis by a gear, which is in mesh with the control rack. An upper and lower helix or cut-off are machined into the lower end of the plunger for metering purposes. Rotation of the plunger, by changing the position of the helix, retards or advances the closing of the ports and beginning and ending of injection period, at the same time increasing or decreasing the desired amount of fuel which remains under the plunger for injection into the cylinder.

Injectors may be one of four different types, each designed for a specific requirement. The correct injector must be used and the type can be determined by checking the injector in service for the number which appears on a color tag pressed into the body.

Injector Mounting

The injectors are mounted in the cylinder head with their spray tips projecting slightly below the top of the inside surface of the combustion chambers, Figs. 2, 3. A clamp, bolted to the cylinder head and fitting into a machined recess in each side of the injector body, holds the injector in place in a water-cooled copper tube which passes through the cylinder head. A dowel pin in the injector body registers with a hole in the cylinder head for the purpose of accurately locating the injector.

The copper tube is installed in the cylinder head with a seal ring at the flanged upper end. The lower end is peened into a recess of the cylinder head. The tapered lower end of the injector seats in the copper tube, forming a tight seal to withstand the high pressure inside the combustion chamber.

Injector Service

Cleanliness is absolutely essential in

Fig. 1 Fuel injector assembly

Fig. 2 Fuel injector mounting on Series 71 In-Line engines

servicing injectors because practically all injector service troubles are directly traceable to dirt, grit or other foreign matter. When preparing to assemble an injector, therefore, wash hands thoroughly and clean all parts with clean fuel oil or carbon tetrachloride. Parts should then be blown dry with dry compressed air, making sure to blow through all passages in the injector body as well as drilled holes and slots.

When more than one injector is disassembled, it is necessary to keep the component parts of each one together. The plunger must always be fitted with the same bushing.

After injectors have operated in an engine the filter caps and filters should not be removed when the injector is in the engine. Should it become necessary to remove these parts, the injector must be removed from the engine and completely disassembled and cleaned.

Whenever an injector has been removed and reinstalled, or a new injector installed, the injectors must be timed and the racks positioned as outlined in the *Tune Up* section of this chapter.

Fig. 3 Fuel injector mounting on V-71 engine

Injector Removal

1. Remove valve rocker cover.
2. Remove fuel pipes from injector and fuel connectors. *To prevent dirt entering injector, cover each fuel fitting with a shipping cap.*
3. Turn engine over with a bar to bring outer ends of push rods of injector and valve rocker arms in line horizontally.
4. Remove two rocker shaft bracket bolts and swing rocker arm assembly away from injector and valves.
5. Remove injector clamp nut, washer and clamp.
6. On V-71 engines, loosen inner and outer adjusting screws on injector rack control lever and slide lever away from injector.
7. On all engines, lift injector from its seat in the cylinder head with tool shown in Fig. 4, and disconnect control rack linkage.

Fig. 4 Removing injector

8. Cover injector hole in cylinder head to keep out dirt.
9. Clean exterior of injector with clean fuel oil and dry with compressed air.

Injector Testing

Before putting an injector into service, a series of tests must be made on special testing equipment made for the purpose. Those who have this equipment are provided with complete instructions for its use. Therefore, there is no need to go into the various procedures for those who do not have the apparatus.

Injector Disassembly

Cleanliness and freedom from dirt at the workbench is absolutely essential. Work must be done in a clean room with clean fuel. Always use paper cleaning tissue to clean and dry parts—do not use rags.

1. Support injector upright in a suitable fixture or a bench vise with special jaws, Fig. 5, and remove filter caps, springs, filter elements and gaskets. *Discard filter elements and gaskets and use new ones on reassembly.*
2. Compress follower spring. Then, using a screwdriver, raise spring above stop pin and withdraw pin. Allow follower spring to rise gradually.
3. Remove follower, spring and plunger as a unit.
4. Reverse injector in fixture and loosen nut from injector body.
5. Lift injector nut straight up by hand, being careful not to dislodge the spray tip and valve parts. Remove spray tip and valve parts off bushing and place in a clean receptacle until ready for reassembly. When an injector has been in use for some time, the spray tip, even though clean on the outside, may not be pushed readily from the nut with the fingers. In this event, support the nut on a wood block and drive the tip down through the nut, using a suitable drift.
6. Remove spill deflector and seal ring from injector nut.
7. Remove plunger bushing, gear retainer and gear from injector body.
8. Withdraw injector control rack from injector body.

Fig. 5 Injector mounted in special vise jaws. Slotted tool is used to lift plunger spring so stop pin can be withdrawn

Fig. 9 Cleaning injector plunger bushing with Tool J-1291-01 and tissue paper

Cleaning Injector Parts

Since most injector troubles are the result of dirt particles, it is essential that a clean area be provided on which to place injector parts after cleaning and inspection.

Wash all parts with clean fuel oil or a suitable cleaning solvent and dry with clean, filtered compressed air. Do not use waste or rags for cleaning purposes. Be sure to clean out all passages, drilled holes and slots in all injector parts.

1. Spray tip should be cleaned with Reamer J-1243, Fig. 6. Turn reamer in a clockwise direction to remove carbon deposits. Wash spray tip and dry with compressed air. Clean spray tip orifices, Fig. 7, using a .005″ reamer wire for tips with .005″ or .0055″ diameter holes, or a .006″ diameter wire for tips with .006″ diameter holes.
2. However, before using wire, hone end of wire until it is smooth and free of burrs, and taper end a distance of $\frac{1}{16}$″, using Stone J-8170. Allow wire to extend ⅛″ from Tool J-8169. Wash spray tip in clean fuel oil and dry with compressed air after cleaning orifices.
3. Clean and brush all passages in injector body, using special fuel oil cleaning brush J-8152 and rack hole cleaning brush J-8150. Blow out passages and dry with compressed air.
4. Carefully insert reamer J-4986-1, Fig. 8, in injector nut. Turn reamer in a clockwise direction to remove carbon deposits. Use care in reaming to prevent removing any metal or setting up burrs on spray tip seat. Then, wash in clean fuel oil and dry with compressed air. Carbon deposits on the spray tip seating surface of the injector nut will result in poor sealing and consequent fuel leakage around spray tip.
5. When handling the injector plunger, do not touch finished plunger surfaces with the fingers. Wash plunger and bushing with clean fuel oil and dry with compressed air. Final cleaning may be accomplished with soft tissue paper. Wrap tissue around tool J-1291-01 and clean out bushing bore, Fig. 9. Keep plunger and bushing together as they are mated parts.
6. After washing, submerge parts in a clean receptacle containing clean fuel oil. Keep parts of each injector assembly together.

Assemble Injector

Refer to Figs. 10, 11 and 12 for proper relative position of injector parts. Since the plunger and bushing are matched parts, they must be considered as one piece and, if one is replaced, both must be replaced.

Assemble Filters—New filters and gaskets should always be used when reassembling injectors.

1. Holding injector body right side up, place a filter in each of the fuel cavities in the top of the injector body, Fig. 10. *Note that the filters have a dimple in one end; always have the dimple at the bottom.*

Fig. 10 Fuel injector filters and related parts

Fig. 11 Fuel injector rack and related parts

2. Place a spring above each filter, a new gasket up against the shoulder of each filter cap, lubricate the threads, and tighten the cap in place to a torque of 65-75 ft lbs, using a $\frac{9}{16}$″ deep socket wrench. *It is important that the filter caps be tightened securely so as to compress the gaskets and effect a good seal with the injector body. Also, when the caps are tightened, they compress the filter springs which hold the filters securely in place so all fuel entering the injector is properly filtered.*

Fig. 12 Fuel injector plunger and related parts

Fig. 13 Checking fuel injector spray tip concentricity with Gauge J-5119

3. Install shipping caps on filter caps to prevent any dirt particles from entering injector. Be sure shipping caps are clean.

Assemble Rack and Gear—Refer to Fig. 11 and note that two of the teeth of the rack have a drill spot mark; also note one tooth of the mating gear is similarly marked. When rack and gear are assembled, the mark tooth of the gear must be engaged between the two marked teeth on the rack.

1. Hold the injector body bottom end up and slide the rack through the proper hole in the body. The two marked teeth can then be observed when looking into the bore for the gear from the bottom of the injector body. *The rack can be placed in the body in only one position and have the tooth marks show in the opening for the gear.*
2. Hold rack in position so the tooth marks show and slide the gear into proper engagement with the rack.
3. Slide gear retainer down on top of gear. Then place plunger bushing down onto retainer with locating pin in bushing guided into slot of body.

Assemble Valve and Related Parts

1. Referring to Fig. 11, support body in holding fixture with bottom end up.
2. Locate seal ring on shoulder of body. Slide spill deflector over barrel of bushing.
3. Place valve seat on end of bushing. Insert stem of valve in one end of its spring and stop in opposite end of spring. Lower cage over this assembly so that the stop seats in cage; then position cage assembly on valve seat.
4. Locate check valve centrally on cage and place spray tip over check valve and against cage.
5. Lubricate threads and carefully pilot nut over spray tip and check valve. The tip will slide through hole in small end of nut.
6. Screw nut in place by hand, making sure valve assembly does not shift. *Do not use wrench to tighten nut at this time. If valve parts are not centrally located, they will not enter counterbore of nut. To facilitate assembly in such cases, turn end of spray tip with fingers while screwing nut into body by hand.*

Assemble Plunger and Follower

1. Referring to Fig. 12, slide head of plunger into follower. Insert this assembly through plunger spring for assembly to injector.
2. Invert injector in the holding fixture, connector side up, and push rack all the way in. Then insert free end of plunger into top of injector body.
3. Start the stop pin into position into the body so that bottom coil of follower spring rests on narrow flange on stop pin. Then with slot in follower and hole in injector body in alignment for the stop pin and flat side of plunger positioned to engage flat side of gear, press down on top of follower and at the same time press follower stop pin into position with the thumb. The stop pin will slip into position as soon as the slot in follower and hole in body are in alignment. When in place, spring will hold stop pin in position.
4. Invert injector in holding fixture and by means of a socket wrench and torque wrench, tighten injector nut to a torque of 55-65 ft lbs. *Do not exceed specified torque as to do so will cause the plunger to bind in the bushing.*

Check Spray Tip Concentricity—The spray tip and injector nut must be concentric within .008″ to ensure correct alignment of the spray tip in the spray tip hole in the cylinder head (or injector hole tube). A special dial gauge, Fig. 13, is available to make this check.

1. Place injector in concentricity gauge, Fig. 13.
2. Adjust dial indicator to "O". Rotate injector 360 degrees and note total run-out as indicated on dial.
3. If total run-out exceeds .008″, remove injector from gauge. Loosen injector nut, re-center spray tip, tighten nut and recheck concentricity. If, after several attempts, the spray tip cannot be positioned satisfactorily, the assembly of the complete injector must be checked.

Install Injector

1. Insert injector into injector tube with locating dowel registering with locating hole in cylinder head and with pin on injector control tube lever registering with control rack lever.

Fig. 14 Layout of fuel pump parts (right hand pump shown)

2. Place injector clamp over stud. Install special washer and nut and tighten nut to a torque of 20-25 ft lbs. Check to make sure clamp does not interfere with valve or injector springs. *Check injector rack for free movement. Excess torque will cause injector control rack to stick or bind.*
3. Move rocker arm assembly into position and secure bracket bolts to a torque of 90-100 ft lbs (50-55 on V-71's).
4. Remove shipping caps and connect fuel pipes to injector and fuel connectors.

As a precautionary measure against any possibility of scoring injector parts upon initial installation due to lack of lubrication, any entrapped air should be bled from the injector before tightening the connections on the fuel outlet side of the injector. This may be accomplished by cranking the engine briefly with the injector rack in the "no fuel" position and then tightening the fuel pipe connection. When installing injector fuel lines, connections should be tightened only enough (12-15 ft lbs) to prevent leakage of fuel. Excess tightening may result in the flared end of the fuel line being twisted or fractured. When all injector fuel lines are installed, the engine should be run long enough (during tune-up procedure) to check for leaks. Should leaks occur, the connections should be tightened only enough to stop the leak.

Following installation of the injectors, a complete engine tune-up should be performed as outlined in the *Tune-Up* Section of this chapter. However, if only one injector has been replaced, and other injectors and governor adjustments have not been disturbed, it will only be necessary to adjust the clearance of the valves and time the injector for the one cylinder, and then position the control racks as outlined in the *Governor* section of this chapter.

FUEL OIL PUMP

The fuel pump, Fig. 14, is of the positive displacement, gear type. The pump is attached to the blower and is driven off the rear end of the blower lower rotor. The pump gears have a press fit on the driven and drive shafts.

A spring-loaded relief valve incorporated in the pump body normally remains in the closed position, operating only when pressure on the outlet side (to fuel filter) becomes excessive due to a plugged filter or fuel line. The valve will open at a pressure of approximately 65 to 70 psi, allowing fuel to return through a passage in the body from the pressure side to the suction side of the pump.

Removal

If the pump fails to rotate when the blower is running, the cause may be due to a broken drive fork on the end of the pump shaft.

To remove the pump, disconnect the intake and discharge lines from the pump. Unfasten the pump from the rear blower end plate and withdraw it straight out. After the pump has been removed, rotate the shaft by hand to see if the parts rotate freely. If the pump is binding or sticking, it should be replaced with a new pump.

Disassembly

When disassembling the pump the drive shaft must not be pulled from the pump seals unless a special tool is available for guiding the drive shaft back into the seals. If such a tool is not used, the end of the shaft will destroy the leather sealing edges and the pump will leak excessively.

During disassembly, note that the idler gear is held to the shaft by a ⅛" steel ball. If an oil seal pilot tool is not available, the drive shaft must not be removed. Pull the shaft from the body only until the steel ball can be removed from between the gear and shaft.

Assembly

Using Fig. 14 as a guide, assemble the pump in the reverse order of its disassembly. When positioning the drive gear over the drive shaft, see that the open end of the ball slot is toward the cover. After assembling the driven gear to the short shaft with the steel ball locking the gear to the shaft, install the assemin the gear toward the cover.
bly into the pump body with the ball slot

Install

Install the pump to the blower rear end plate so the relief valve retainer screw is toward the cylinder block.

FUEL MANIFOLDS

Series 53, 6V-53, V-71

The fuel manifolds in these engines are an integral part of the cylinder heads.

In Line 71 Engines

Fuel injectors are supplied with fuel oil through the lower of the two fuel manifolds located on the side of the cylinder head and connected to the injectors by short steel lines. The upper manifold returns excess fuel from the injectors through tubing to the fuel tank. Both manifolds are locked in position at the side of the cylinder head by fuel connectors which set into tapered seats in the manifold fittings. When a connector is removed, use care to see that the tapered seats are perfectly clean and properly positioned in the manifold fittings.

When reinstalling manifolds, centralize the T connectors with the fuel connectors by alternately turning the connectors and moving manifold. This is important in order to insure leak-proof joints. Tighten fuel connectors equally and secure lock nuts against new copper washers. The lock nuts contain a fibre insert which seals the threads against leakage. Install the nut with the fibre insert *down* against copper washer and tighten to 30-35 lbs. ft. torque.

Before replacing the valve cover, run the engine and see that all fuel line connections are tight so that no fuel oil leaks into the cylinder head to dilute the lubricating oil. If lubricating oil is diluted with fuel oil, engine bearings will be seriously damaged. Any leakage between tapered seats and fuel connectors would be observed at the holes on the outside of the cylinder head.

Engine Repair Section

CYLINDER HEAD

Remove & Install

Due to the various optional and accessory equipment used on the different engine models, only the general steps for removing and installing the head are covered. If the engine is equipped with special accessories other than those mentioned below, carefully disconnect or remove those affecting cylinder head removal, making sure to note their position to assure correct installation.

Series 53, 6V-53, V-71

1. Disconnect exhaust piping at exhaust manifold.
2. Drain cooling system.
3. Disconnect fuel lines at cylinder head.
4. On Series 53 and 6V-53, loosen clamp and slide hose back on thermostat housing. Remove thermostat and its housing.
5. Remove rocker arm cover (also governor cover on V-71).
6. Disconnect and remove fuel rod between governor and injector control tube lever.
7. On Series 53 and 6V-53, remove fuel rod cover (if used). On V-71, loosen fuel rod cover hose clamp and slide hose up on fuel rod cover toward governor.
8. Remove exhaust manifold.
9. Remove injector control tube and brackets as a unit. If the head is to be stripped for valve or other service operations, the fuel lines and injectors should be removed at this time.
10. Remove head stud nuts and bolts. Then use a suitable sling to lift head off block. *On V-71, if interference is encountered between rear end of right cylinder bank and any of the flywheel housing attaching bolts, loosen the bolts to facilitate removal of the head. Caution: When resting head on work bench, protect cam follower rollers and injector spray tips by resting valve side of head on wooden blocks.*
11. Remove cylinder head compression gaskets, oil seals and water seals, Fig. 1.

Fig. 1 Cylinder head with four exhaust valves per cylinder. Series 53, 6V-53, V-71

Installation

1. Install new compression gaskets, oil seals and water seals.
2. To install cylinder head on In-Line 53 engines without disturbing gaskets and seals, special guide studs (J-7866) must be used. They should also be used to facilitate cylinder head installation on 6V-53 engines. Install the guide studs diagonally opposite in end cylinder block bolt holes.
3. A final visual check of all cylinder head gaskets and seals should be made to ensure that they are in place just before cylinder head is lowered onto cylinder block. *This is a very important check as compression gaskets or seals which are jarred out of their proper position will lead to leaks and "blow-by" with resultant poor engine performance and damage to engine.*
4. The cylinder head must be gradually and uniformly drawn down against the gaskets and seals to ensure a good seal between head and block.
5. On In-Line 53 engines equipped with both 6 and 12 point head bolts, *the 12 point bolts must be installed on the camshaft side of the head to eliminate possible interference between governor control link and head bolt.*
6. Install head bolts and stud nuts. Then, beginning on the camshaft side of head, take up tension in cam follower springs by tightening bolts and nuts lightly.
7. Finally, tighten bolts and nuts to the specified torque about ½ turn at a time in the sequence shown in Fig. 3. Under no circumstances should the torque exceed the specified limits, otherwise the studs and bolts may become stretched beyond their elastic limit.
8. Install fuel injectors.
9. Set injector control tube assembly in place on cylinder head and tighten hold-down bolts finger tight. When positioning injector control tube, be sure that ball end of injector control rack levers engage slots in control racks. With one end of control tube return spring hooked around control tube bracket, tighten bracket bolts to 10-12 ft-lb torque.
   jector racks out (no fuel position) after they have been moved all the
10. After tightening bolts, revolve tube and see if return spring pulls injector racks out (no fuel position) after they have been moved all the way in to the full fuel position. Since the injector control tube is mounted in self-aligning bearings,

Fig. 2 Cylinder head with four valves per cylinder. Series 71 In-Line engines

Fig. 3 Cylinder head tightening sequence

tapping the tube lightly with a soft hammer will remove any bind that exists. *The injector racks must return to the no fuel position freely by aid of the return spring only. Do not bend the return spring to bring about this condition.*

11. Install fuel rod, exhaust manifold, thermostat, water hose and fuel lines. Fill cooling system and check for leaks.
12. With throttle in off position, hand crank engine to be sure all parts function freely.
13. After starting engine, see that all fuel line connections are tight. After engine has reached operating temperature, check cylinder head bolt and nut torque and recheck valve lash. Tune up engine as outlined in the *Tune Up Section* of this chapter.

Series 71 In-Line Engines

1. Disconnect exhaust piping at exhaust manifold. On turbocharged units, remove connections from exhaust manifold to turbocharger. Remove turbocharger if necessary.
2. Remove air cleaners.
3. Drain cooling system. Be sure to remove vent plug in thermostat housing when draining system.
4. Remove rocker arm cover.
5. Remove thermostat and its housing.
6. Remove temperature gauge unit from adaptor at rear of water outlet manifold.
7. Disconnect air inlet pipe from elbows at cylinder head and cylinder block hand hole cover.
8. Remove fuel filter if attached to cylinder head.
9. Disconnect governor fuel rod from injector control tube lever.
10. Remove governor cover.
11. Remove control link from differential lever on mechanical governor.
12. Unfasten and lift injector control tube away from cylinder head.
13. Remove fuel lines from injectors and fuel connectors, Fig. 2. *Cover each injector opening with a shipping cap or other suitable plug to prevent dirt from entering injectors.*
14. Loosen rocker arm bracket bolts to facilitate their removal after head is removed.
15. Remove two bolts securing lifter bracket to balance weight cover; also the two bolts securing rear lifter bracket to flywheel housing. At the same time, loosen the two bolts directly below each lifter bracket which attach the balance weight cover and flywheel housing to the front and rear end plates. *If these bolts are not loosened, their threaded ends may bear against ends of cylinder head and thus interfere withs its removal.*
16. Remove cylinder head stud nuts.
17. With lifting hooks inserted in lifter brackets, raise cylinder head uniformly from block.
18. Remove compression gaskets and oil and water seals, Fig. 2.
19. Do not set head with bottom face down on work bench as the cam followers project below bottom of head. Injector spray tips also project if injectors have not been removed. Set head on its side.

Installation

1. Place new cylinder liner compression gasket on each cylinder liner.
2. Place new seal rings in counterbores of water and oil holes in cylinder block, Fig. 2.
3. Install new oil seal in groove around perimeter of cylinder block. Do not stretch.
4. Lower head in place over studs. *A final visual check of all gaskets and seals should be made to be sure they are in place just before head is lowered in place. This is a very important check as compression gaskets and oil seals which are jarred out of position will lead to leaks and "blow-by" with resultant poor engine performance and damage to engine.*
5. After setting head in place, loosen lifter bracket attaching bolts before installing head stud nuts. If this is not done, cylinder head may be prevented from seating properly against its gaskets and cylinder block. A similar condition could exist when installing a head on an engine with the exhaust manifold attached to the head. Clearance must be assured between exhaust manifold and bosses on cylinder block. On some models, these bosses serve as a rest for the exhaust manifold *after* the head has been attached to the block.
6. The head must be gradually drawn down against the head gaskets and seals to assure a good seal between all engine systems.
7. Use hypoid grease on threads of studs and that portion of head that nuts contact.

8. Beginning on camshaft side, first take up tension of cam follower springs and draw nuts down finger tight. Then tighten with a socket wrench. Finally, draw nuts down to the proper torque ½ turn at a time to ensure uniform compression of gaskets. Each of the above three steps should follow the sequence shown in Fig. 3. Torque should not exceed the specified limits, otherwise the studs may become stretched beyond their elastic limits.
9. Tighten the two flywheel housing attaching bolts directly below rear lifter bracket.
10. Using a new gasket, secure rear lifter bracket to head and flywheel housing. Tighten bolts to 55-50 ft-lb (cast iron engine) or 35-40 ft-lb (aluminum engine). Install front lifter bracket in same manner and to the same torque.
11. Connect fuel pipes.
12. Install governor.
13. Install injector control tube assembly as directed for Series 53 engines.
14. Install remaining items in reverse order of removal. Then, with throttle in off position, crank engine to see that all parts function freely.
15. Tune up engine as outlined in the *Tune Up Section* of this chapter.
16. Start engine and check fuel line connections for leaks. After engine has reached operating temperature, recheck cylinder head torque and valve lash. Examine all fuel oil and lubricating oil connections for leaks.

VALVE & INJECTOR OPERATING MECHANISM

Service Note

Several operations may be performed on the valve mechanism, Fig. 4, without removing the cylinder head from the block. The operations not requiring cylinder head removal are:

1. Adjust valve clearance.
2. Remove and install valve spring.
3. Remove and install a rocker arm.
4. Remove and install a rocker arm shaft or bracket.
5. Remove and install an injector.

It is also possible to remove or replace a push rod, push rod spring, spring seats or cam follower without removing the head. These parts, however, are more easily changed from the lower side of the cylinder head when the head is off the engine.

To remove and install valves, valve guides, valve seat inserts and to recondition valves and seats, the head must be removed.

ROCKER ARMS

1. Remove valve rocker cover.
2. Remove fuel lines from injectors and fuel connectors.
3. Turn engine over in direction of normal rotation to bring push rod outer ends in line horizontally.
4. Remove rocker arm shaft brackets and shaft.
5. Loosen lock nut at upper end of push rod and unscrew rocker arm from push rod.

Fig. 4 Valve and injector operating mechanism

Inspection

1. Wash all parts in clean fuel oil and air dry. Make certain that oil passages in rocker arms, shaft and bracket bolts are open and clean.
2. Inspect all parts for excessive wear. The maximum clearance between rocker arm shaft and injector rocker arm bushing or an exhaust valve rocker arm (which has no bushing) is .004" with used parts.
3. Examine each rocker arm contact face for wear or galling. Also inspect contact surfaces of exhaust valve on four valve cylinder heads.

Fig. 5 Cam roller wear and clearance diagram

Installation

1. Install cylinder head, if removed.
2. Apply clean oil to outer surface of rocker arm shaft.
3. Install rocker arms and shaft by reversing the sequence of operation for removal. Tighten bracket bolts to 50-55 ft-lb. *Caution: On four valve engines, there is a possibility of damaging valves if the valve bridges are not resting on the ends of the valves when tightening the shaft bracket bolts. Therefore, note the position of the bridges before, during and after tightening bracket bolts.*
4. Connect fuel lines to injectors and fuel connectors.
5. Adjust valve lash and time fuel ininjectors as outlined in the *Tune Up Section.*
6. While engine is running in preparation for final tune-up, inspect fuel lines for leaks.
7. After engine reaches operating temperature, perform final engine tune-up.

CAM FOLLOWERS

When any appreciable change in injector timing or exhaust valve clearance occurs during engine operation, cam followers and their related parts, Fig. 4, should be inspected for excessive wear. This change in injector timing and valve clearance during engine operation can usually be detected by excessive noise at idling speed.

Cam followers may be removed from either the top or bottom of the cylinder head. Of course, when followers are removed from the bottom, removal of the head will be necessary. When they are removed from the top, a special tool (J-3092-01) is required to extract push rod and cam follower from its bore after removing the push rod spring seat retainer. Herewith is the procedure for removal with head off.

1. Rest cylinder head on its side and remove cam follower guide, Fig. 4.
2. Pull cam followers from head.
3. Remove fuel lines from injectors and connectors.
4. Loosen lock nuts at upper end of push rods and unscrew push rods from rocker arm clevises.
5. Pull push rod and spring assemblies from bottom of head.
6. Remove push rod lock nut, upper and lower spring seats from each push rod for cleaning and inspection. *The upper push rod spring retainers remain in head. If head is to be changed these retainers must be removed; if not they may be left in place.*

Inspection

1. Clean all parts thoroughly with fuel oil and dry with compressed air.
2. Inspect rounded ends of push rods for wear. Also check push rods for straightness; replace any rod that is bent.
3. Check push rod spring tension to determine if it is able to maintain the proper load on the cam follower. Any spring that does not conform to the specifications listed in the *Valve Specifications* chart should be discarded.

Fig. 6 Installation of cam follower

Fig. 7 Installation of valve and seat insert for V-71 engines

Fig. 8 Installation of valve and seat insert for In Line 71 four valve engines

Fig. 9 Installation of valve and seat insert for In-Line 71 two valve engines

4. Cam follower holes in the cylinder head should be examined to make sure they are clean, smooth and free of score marks so as to permit proper functioning of cam followers. Any existing score marks should be cleaned up.
5. Clearance between cam follower and cylinder head bore should be .001-.003". If clearance exceeds .006", install new cam followers.
6. Cam rollers must turn smoothly and freely on their pins, and rollers must be free of flat spots or scuff marks. If rollers do not turn freely or have been scored or worn flat, then the cams on which they operate should be examined. If cams are excessively worn or damaged, the camshaft must be replaced.
7. Measure clearances as indicated in Fig. 5. If clearances exceed those shown, replace followers.

Installation

1. Referring to Fig. 4, assemble in turn over push rod, lower spring seat, push rod spring, upper spring seat and push rod lock nut.
2. With upper spring seat retainer in place in head, slide push rod assemblies into position from bottom of head.
3. Screw push rod lock nut down on upper end of rod as far as possible, and screw push rod into clevis until end of rod is flush with or above inner side of clevis.
4. Note oil hole at bottom of follower, Fig. 6. With this hole pointing away from valves, slide followers into position from bottom of head. *To insure initial lubrication of the follower roller pin, immerse cam followers in clean lubricating oil for at least five minutes before installing them in cylinder head.*
5. Secure follower guide to cylinder head. Then check to be sure there is clearance between cam follower legs and guide.

EXHAUST VALVES & SEATS

See Figs. 7 to 11 for valve and valve seat installation requirements. As shown in the illustrations, a new valve must not protrude more than the specifications shown beyond the surface of the cylinder head. After several valve reconditioning operations, the valve seat insert diameter will be increased so that the valve will recede into the head.

VALVE GUIDES

If the clearance between valve stem and guide exceeds the limits given in the *Valve Specifications* chart, the old guides may be driven out and new ones driven in.

When installing the new guide, locate it squarely in the cylinder head and tap gently to start it in place. With the guide properly started, drive it in until its upper end is .010 to .030" *below* top of cylinder head on Series 53, 6V-53 engines. On four valve Series 71 In-Line and V-71 engines, valve guide position should be 7/8" *above* top of cylinder head; on two valve engines, $1\frac{19}{32}$" above top of head.

On current In-Line 71 engines, valve guides, when installed, will be flush with the lower end of the valve guide boss in the head. This will provide $\frac{1}{32}$" to 1/8" clearance between top of deflector on rotating-type valve and the bottom of valve guide.

Fig. 14 Driving injector copper tube out of cylinder head

Fig. 15 First phase of injector copper tube installation

Fig. 16 Second phase of injector copper tube installation

Service replacement guides are finish reamed during manufacture and, therefore, do not require reaming after installation.

INJECTOR TUBES

The bore in the cylinder head for the fuel injector is directly through the cylinder head water jacket as shown in Fig. 12. To prevent cooling water from contacting the injector and still maintain maximum cooling of the injector, a tube is pressed into the injector bore. This tube is sealed at the top with a neoprene ring and upset with a flare on the lower side of the cylinder head to create watertight joints at the top and bottom.

Early design four-valve cylinder heads did not incorporate an injector tube. The injector seated directly into a machined opening in the cylinder head.

Removal

Support the cylinder head with the top side up and screw the special tap shown in Fig. 13 into the copper injector tube. Invert the cylinder head and insert the driving rod, Fig. 14, through the spray tip opening of the tube until it rests against the tap. Then drive the copper tube and tap out of the cylinder head.

Installation

Installation of the copper tube requires careful inspection to make sure that the area of the cylinder head is clean so that when the tube contacts the metal of the cylinder head, foreign material will not prevent it from seating at the bottom and top ends.

To install the tube, first position the seal ring in the counterbore. Then work the injector tube through the seal ring and into the bore of head. Insert the driving tool, Fig. 15, in the tube and drive the tube into the position. When the tube is properly located, the flange at the upper end will seat on the seal ring and into the bore of the head.

After driving the tube into position, swage the lower end at the spray tip with the equipment shown in Fig. 16.

Support the edge of the cylinder head and install the driving tool inside the copper tube. Then install the flaring tool and T-handle over the lower end of the driving tool and upset the copper tube into the counterbore at the lower side of the cylinder head.

Reaming Copper Tube

After the copper tube has been installed in the cylinder head, it must be reamed to receive the injector body nut and spray tip and for good seating of the bevel on the lower end of the injector nut.

Reaming of the upper end of the tube to the proper size for the body nut and lower end of spray tip is accomplished by the tools shown in Fig. 17.

Reaming Bevel Seat

In order to withstand the high compression pressure, the beveled seat at the lower end of the injector nut must fit true in the copper tube. This is accomplished by reaming, Fig. 18. After the reaming operation, daub a thin film of Prussian Blue on the lower flared end of the injector nut and insert the injector down into the tube and lock in position temporarily with injector crab. Then remove the injector and see if it has a good bearing at the beveled seat. If the bearing is poor at this point, the chances are that the tube has been improperly installed, in which case install another tube and again proceed with the reaming operation.

Fig. 17 Reaming injector copper tube

Fig. 18 Reaming injector copper tube beveled seat for spray tip

TIMING GEARS

Figs. 19 to 22 illustrate the gear train and timing marks for the various engines. The correct relationship between crankshaft and camshaft must be maintained to control fuel injection properly and the opening and closing of the exhaust valves.

The crankshaft timing gear can be mounted in only one position due to its being keyed to the crankshaft. The camshaft gear can also be mounted in only one position as a result of the location of the keyway relative to the cams. Therefore, when the engine is properly timed, the markings on the various gears will match as shown in the illustrations.

CAMSHAFT

Figs. 23, 24 and 25 illustrate disassembled views of the camshaft and balance shaft and related parts. In servicing camshaft, gears and related parts, clean all parts with fuel oil and dry with compressed air. Be sure that oil holes in camshaft end bearings are clean and open. Inspect components as follows:

1. Inspect cams and journals and if they are badly scored or worn, replace the camshaft. If cams are scored, the cam followers should also be inspected.

Fig. 19 Gear train and timing marks. Series 53 In-Line engines

Fig. 20 Gear train and timing marks. 6V-53 engines

2. Examine both faces of camshaft rear end bearing and thrust washers. If either face is scored or if thrust washers are worn excessively, replace the washers. Also, examine surfaces of gear and camshaft which the thrust washers contact; if these surfaces are scratched but not severely scored, they may be smoothed down with an oil stone. However, if score marks are too deep to be removed or parts are badly worn, new parts must be used.
3. Clearance between thrust washer and thrust shoulder of camshaft or balance shaft, using new parts, is from .004″ to .012″, or a maximum of .018″ with new parts. Thrust washers are available in .005″ and .010″ oversize and may be used to reduce excessive clearance to within .004" to .012".
4. The clearance between new camshaft end journals and their respective new bearings is from .0025″ to .004″, or a maximum of .006″ with worn parts. End bearings are available in .010″ or .020″ undersize for use with shafts which have worn or been reground and the clearances exceed the specified .0025″ to .004″ limits.
5. The clearance between camshaft journals and the intermediate bearings is from .0025″ to .005″ with new parts, or a maximum of .009″ with worn parts. Camshaft intermediate bearings are available in .010″ and .020″ undersize for use with worn or reground shafts in which the clearances exceed the limits of .0025″ to .005″.
6. If any of the bearings are scored or worn so that the clearances exceed the specified limits, install new bearings.
7. Check bushings in end bearings for evidence of turning in the bearings. If bushings have turned, install new bushings and test for a press fit. A proper press fit is indicated if bushing will not move when a 2000-lb end load is applied. Bushings must be finished bored after installation. Also, inside diameter of bushings must be square with rear face of bearing within .0015″ total indicator reading. Camshaft rear end bear-

Fig. 21 Gear train and timing marks. Series 71 In-Line engines

ing bushing must project .045″ to .055″ from each end of bearing.

8. Bushings in camshaft front end bearing do not project from bearing. End of inner bushing in front end bearing should be installed flush with end of bearing; end of outer bushing should be flush with counterbore in bearing.

BLOWER DRIVE GEAR

Series 53, 6V-53

The blower drive gear is keyed and pressed onto a shaft which is supported in a housing attached to the rear end plate on In-Line engines. The gear is driven by the camshaft gear or balance shaft gear, depending upon the engine model and rotation.

On 6V-53 engines, the blower drive support is mounted as shown in Fig. 26, and the gear is driven by one of the camshaft gears.

V-71 Engines

The blower drive gear, Fig. 27, is mounted on the blower drive gear support, which is attached to the cylinder block rear end plate. This gear is driven by the right cylinder bank camshaft gear. Since the camshaft gear runs at crankshaft speed, the blower gear, which has about half as many teeth as the camshaft gear, runs approximately twice engine speed.

The blower gear bearings are pressure lubricated through an external line from the blower rear end plate to the blower drive support. The blower(s) must be removed prior to the removal of the blower drive gear and support assembly.

Remove and disassemble the blower drive gear and support as suggested by Fig. 27. Clean all parts with fuel oil and dry with compressed air. Be sure that oil passage in gear support is clean. Discard thrust washers if worn excessively or otherwise damaged.

Check inside diameter of blower drive gear bearings for wear; also check outside diameter of support hub on which gear bearings ride. The inside diameter of new bearings is 1.6260″ to 1.6265″. Clearance between bearings and support should be .001″ to .0025″ with new parts and a maximum of .005″ with used parts. Install new parts whenever clearances exceed the maximum. Should the check show that excessive wear is present, a new support and bearing asembly should be installed.

When assembling, secure the gear to the support and tighten nut to a torque of 50-60 ft lbs. Bend lugs on lock washer against flats on nut. Check clearance between blower drive gear support thrust washer and blower drive gear thrust bearing. Clearance should be .005″ to .010″ and should not exceed .012″ between worn parts.

If spring plates were removed from blower gear hub, attach and torque bolts to 35-39 ft lbs.

In Line 71 Engines

The blower drive gear, Fig. 28, is attached to the blower drive gear hub and located on the blower side of the engine. The blower drive gear drives the blower and, in turn, the governor, water pump and fuel pump. This drive is cushioned by a spring-loaded flexible coupling, insuring uniform rotation to the blower rotors.

With the blower and drive shaft cover removed, the drive gear assembly may be withdrawn from the front face of the cylinder block end plate after disconnecting the oil pipe and removing two bolts holding the gear hub support to the cylinder block end plate.

Although it may be convenient to remove the blower drive gear assembly without taking off the flywheel housing, it has been found that close inspection of the entire gear train is advisable whenever any one of the gears requires service.

To remove the blower drive gear assembly after the flywheel housing has been removed, loosen the blower from the cylinder block and remove the snap ring from the ring groove in the blower drive cam. Withdraw the shaft from the cam and blower rotor gear hub. Loosen seal clamp and slide seal and clamp back on blower drive cover.

Slide blower assembly rearward, exposing the hub nut at the forward end of the blower drive gear hub. Then check the end clearance between the gear hub bearing and thrust washer with a feeler gauge placed between these parts, Fig. 29. Clearance should be .005″ to .008″ with new parts and .010″ with used parts. A clearance in excess of this is sufficient reason for renewing the gear hub support thrust washer or bearings in support.

When the assembly has been removed and disassembled, check the inside diameter of the bearings for wear and roundness; also check outside diameter of hub for wear. Inside diameter of new bearing is 1.6260″ to 1.6265″. Clearance between bearings and hub should be from .001″ to .0025″ with new parts, or .005″ maximum with used parts. Should the check show that bearings and hub are worn excessively, a new support and bearing assembly should be installed.

PISTON & ROD, REMOVE

Before removing piston and rod assemblies, check for any excessive looseness of piston in cylinder liner. Check for excessive end play of rods on crankpins.

Remove carbon from the upper inside diameter of cylinder liners. Remove bearing caps from rods and push rod and piston assembly up through top of block.

PISTON & ROD, INSTALL

The lower end of each rod as well as the caps are stamped on one side with a number corresponding to the cylinder in which each rod is used. *The marked side of the rod must always be on the blower side of the block.*

CYLINDER LINERS

Prior to Engine Serial 4A-19537 and 6A-16283 the construction of the cylinder block, cylinder head and liner provided for installing the liner into the cylinder block and permitting the liner flange to be seated directly on the counterbore in the block. This construction provided that the liner should be raised above the cylinder block and compression seal was accomplished by using a conventional cylinder head gasket.

Fig. 30 Cylinder liner measurements

Fig. 31 Use of shims for adjusting liner height

Present design provides for greater depth cylinder block counterbore and use of an insert in the block counterbore to provide a seat for the liner flange. This construction provides that the top of the liner flange be below the top of the cylinder block and compression seal is accomplished by the use of individual gaskets at each cylinder. The conventional cylinder head gasket is eliminated, thus the cylinder head rests directly on the cylinder block and is in metal-to-metal contact. Water and oil passages between block and head are sealed with special grommet type rubber gaskets which are installed in the cylinder block counterbores.

When a cylinder liner change is necessary, due to either wear or scoring, the old liner may be removed from the cylinder block and a new liner installed, or the old liner may be honed oversize and reinstalled. New liners are available only in the standard size *inside* diameter. However, .005", .010", .020" and .030" oversize *outside* diameter liners are available for use in cylinder bores which have been oversized to correct distortion or out-of-roundness.

Since the liners are a loose fit, they may be removed easily from the top of the cylinder block by hand, after loosening with a suitable liner removing tool.

With the liners removed from the block, use a 5/8" diameter brass rod or sharpen a hard wood stick 1" square by 12" long to a tapering point with square edges. Clean each of the air ports by inserting the pointed end of the stick or rod in the port and twisting. Resharpen the stick as often as necessary.

After cleaning the ports, examine the inside of the liner around the port area for burrs. If burrs are found, remove with 250 grit emery paper. Burrs must be removed by hand whether liner is to be honed or not. Failure to remove burrs may result in early and costly failure of pistons and rings.

An alternate method of cleaning the ports is to soak the liner in hot caustic soda or lye solution long enough to loosen the carbon deposits. Final cleaning can be acomplished by a bristle brush.

The liners must not taper more than .001" for its full length or be out-of-round more than .0015" when installed. When measuring cylinder liner with dial indicator, measurements must be taken at 10 places as shown in Fig. 30.

When liners have been in service for any length of time, the inside diameter becomes very smooth or glazed. This glaze, if not removed, lengthens the time required to seat new rings. Therefore, even though inspection reveals a liner to be within specifications and honing unnecessary, the glaze must be removed by working a hone up and down in the liner a few times.

Early type liners must protrude .002" to .006" above the cylinder block. And the variation between adjacent liners should not be greater than .002". Shims of .0015", .003", .005" and .015" thicknesses are available for use under the liner flange to obtain proper liner height as shown in Fig. 31.

With the latest type liner, the top of the liner flange must be .0465" to .050" below the top of the block. If the liner depth is not within these limits, and inspection indicates proper installation, the insert or liners or both should be replaced with new parts since no shims or variable thickness inserts are available.

PISTONS

The top of the piston forms the combustion chamber and is designed to displace the air into close proximity to the fuel spray. The underside of the piston head is reinforced with circular ribs. The ribbed head is cooled by lubricating oil forced from the spray jet on top of the connecting rod.

Fig. 32 Connecting rod, piston pin and bearing assembly

A balancing rib is provided on the inside of the bottom of the piston skirt. Because of this design, all pistons are balanced to within .05 lbs., whether the piston is standard or oversize. One or more oversize pistons may be installed in an engine with other standard pistons without effecting balance.

PISTON RINGS

Each piston is fitted with six cast iron rings of the butt joint type. Four 1/8" wide compression rings are placed above the pin and two 3/32" wide special oil control rings are used in each of the two grooves below the piston pin.

The presence of original tool marks on the piston ring surfaces indicates the general absence of wear. Rings should be inspected for free fit in the grooves, side clearance and wear.

New piston rings should always be used with new pistons. Furthermore, if the engine has been in service for some time, even though the same pistons are again used, it is advisable to use new rings.

PINS & BUSHINGS

Each piston boss is lined with a bronze bushing which serves as a bearing for the piston pin which floats in the piston and connecting rod. The bushing has helical oil grooves for passage of oil from the connecting rod bushing. The piston pin is held in the piston with a retainer and snap ring at each side of the piston. The retainer prevents lubricating oil, which returns from the sprayed piston head and the grooves in the piston bushings, from reaching cylinder walls.

RODS & BEARINGS

Each connecting rod, Fig. 32 is rifle-drilled for lubrication of the upper end, and is equipped with an oil spray jet for cooling of the piston head.

The lower end of the connecting rod shank is fitted with a plug which meters oil through the rifle-drilled hole.

Rod bearing shells are of the precision type without shim adjustment. The upper and lower halves of the shells are not interchangeable.

A helically - grooved, steel-backed bronze bushing is pressed into each side of the rod upper end for the piston pin bearing. A cavity of $\frac{3}{16}''$ between the inner ends of the bushings registers with the drilled oil passage in the rod.

Rod bearing shells are available in .002″, .010″, .020″, .030″, .040″, .050″ and .060″ undersizes.

MAIN BEARINGS

Main bearing shells are of the precision type and are replaceable without machining. Each bearing cap is marked with a number and when removed must always be replaced in its respective position.

Crankshaft journals may be reground undersize to accommodate undersize bearings of .010″, .020″, .030″, .040″, .050″ and .060″. If the journals have been overheated, the heat-treating will be destroyed and a new crankshaft should be used.

CRANKSHAFT END PLAY

Crankshaft end thrust is taken through two-piece washers on each side of the rear main bearing. If the crankshaft thrust surface has been reground, it is sometimes necessary to install thrust washers of different thicknesses in order to center the crankshaft properly at the main bearing journal. If thrust surfaces were not worn enough to require regrinding, or if worn and ground off equally, then thrust washers of the same thickness should be installed on both sides of the main bearing.

CRANKSHAFT OIL SEALS

Oil seals are incorporated in the flywheel housing cover at the rear and in the cover at the front of the crankshaft. The seal consists of a special treated leather or synthetic ring set into the cover. The rolled-over inner diameter of the seal is held by a coil spring to prevent oil leakage. The crankshaft timing gear at the rear acts as an oil slinger and throws surplus oil from the gear teeth back into a cavity adjacent to the gear. The oil from this cavity flows back into the oil pan. An oil slinger at the front also assists in preventing excessive oil reaching the seal.

OIL PRESSURE REGULATOR

The lubricating oil pressure regulator valve, located at the end of the oil gallery and integral with the oil pump discharge line, consists of a hollow piston-type valve, a compression spring, a plug to retain the spring and the valve body.

The valve is held on its seat by the spring, which is held in compression by the plug screwed into the valve opening in the valve body. The entire assembly is bolted to the lower flange of the cylinder block and sealed against oil leaks by a gasket between the two members.

When conditions are such that oil pressure at the valve exceed 45 lbs., the valve is lifted from its seat and oil from the engine gallery is by-passed to the engine crankcase.

LUBRICATING OIL PUMP

Gear type lubricating oil pumps are used on all engines. On some engines, the oil pump is driven by a roller chain from a sprocket on the crankshaft while on other engines the pump is gear driven.

On gear driven pumps, an idler gear is installed between the drive gear and driven gears. Early style idler gears were attached to a special stud on the crankshaft front cover, while on the latest construction the idler gear is attached directly to the pump.

On engines with chain driven pump, the drive sprocket is installed on the crankshaft and the driver sprocket is supported on the pump drive shaft.

A plunger type relief valve in the pump body by-passes excess oil to the inlet side of the pump when discharge pressure exceeds approximately 100 lbs.

To accommodate either direction of engine rotation and have the flow of oil through the pump in the proper direction, the relief valve assembly may be changed from one side of the pump housing to the opposite side. The pump cover must be properly installed in order to direct oil intake on the correct side of the pump gears.

WATER PUMP

A centrifugal type water pump is used. A bronze impeller is pressed and pinned onto one end of the water pump shaft, and a pump drive coupling and oil slinger is pressed onto the opposite end. The oil slinger shrouds the inner end of the pump body flange to prevent oil from seeping along the shaft and through the shaft bearing. The shaft is supported at the drive end by a sealed, double-row combination radial and thrust ball bearing.

① Models 100 to 300 .030″, models 350 and up .035″.
② Intake 30°, exhaust 45°.
③ With single spring 150 @ 1 13/32″. With dual springs: Inner 50 @ 1 5/32″, outer 135 @ 1 13/32″.
④ Cylinder numbering (front to rear): Left bank 1–3–5–7, right bank 2–4–6–8.
⑤ Inner spring 57 @ 1 5/32″, outer spring 102 @ 1 1/5″.
⑥ Midway between marks on damper.
⑦ On trailing edge of notch on damper.
⑧ Inner spring 95–100 Lbs. @ 1.065. Outer Spring 117–127 Lbs. 1.146.
⑨ Cylinder numbering (front to rear): Left bank 1–3–5, right bank 2–4–6.
⑩ Cylinder numbering (front to rear): Left bank 1–3–5–7–9–11, right bank 2–4–6–8–10–12. Firing order, 1–4–9–8–5–2–11–10–3–6–7–12.
⑪—Series 100 to 300, C46; series 350 to 450, C44.
⑫—Series 100 to 300, C45; series 350 to 450, C44.
⑬—AC. Normal service.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

Gasoline Engine Section

CYLINDER HEAD, REPLACE

In Line Six-Cyl. Engines

Cylinder head bolts should be tightened down in the order shown in Figs. 1 and 2 with a torque wrench. Uniform tightening of head bolts is essential in securing proper gasket seal. Over-tightening may cause distorted block or head, and in extreme instances block and head may crack, bolts may break or threads strip.

Irregular or under-tightening usually results in water leaks or blown gaskets, or other damage may result from the pressure of water in the combustion chamber.

Tighten the bolts in proper sequence when the engine is cold. Then run the engine until the head is at normal operating temperature and give the bolts a final tightening to the torque load given in the *Engine Tightening* table.

V6 and V12 Engines

After installing cylinder head, run engine until normal operating temperature is reached. Then tighten cylinder head bolts in the sequence shown in Fig. 3 to the torque given in the *Engine Tightening* table. After head is properly tightened, adjust valve lash to the recommended clearance on V6 engines.

V8-288, 316, 336, & 347

1. Drain cooling system.
2. Remove air cleaner.
3. Remove radiator hose or leave it attached to water outlet and disconnect outlet from manifold and move it out of the way.
4. Disconnect heater hose from fitting, remove nut retaining hose bracket to manifold and move hose and bracket out of the way.
5. Disconnect wires from generator and remove wire harness from clip on generator end plate.
6. Remove screws retaining generator mounting bracket to manifold.
7. Remove bolt retaining generator adjusting strap and take off generator.
8. On vehicles with power steering, remove screws retaining power steering pump to timing chain cover. Lay pump, with hoses attached, on left fender skirt *but first disconnect battery ground strap to prevent pump from grounding "BAT" terminal of regulator.*
9. Remove fuel pump-to-filter pipe.
10. Unfasten vacuum pipe clip from left cylinder head.
11. Remove vacuum pipe connecting vacuum pump to carburetor. *On vehicles with power brakes, remove vacuum pipe connecting carburetor to power brake hose.*
12. Disconnect wires from coil.
13. Disconnect right cylinder head spark plug wires and wire support and distributor primary wire. Remove distributor cap and lay cap and wires on left side of engine.
14. Remove distributor-to-carburetor vacuum pipe.
15. Disconnect throttle rod from carburetor.
16. Remove screws retaining throttle control engine bracket assembly to manifold (Hydra-Matic models) and tie the bracket and throttle rod against firewall.
17. Remove thermogauge engine unit.
18. Remove intake manifold retaining screws and nuts and take off manifold and gaskets.
19. Remove push rod cover.
20. Remove rocker arm cover. *On left bank remove spark plug wires and wire support.*
21. Remove battery ground strap from left head or engine ground strap from right head.
22. Remove Hydra-Matic oil level indicator tube bracket and engine oil level indicator and tube from right head.
23. Loosen all rocker arm adjusting nuts and move rocker arms off push rods.
24. Remove push rods and place in a suitable stand so they can be replaced in exact position from which they were removed.
25. Remove screws attaching exhaust crossover pipe to manifold.
26. Remove screws from cylinder head water inlet fitting.
27. Remove cylinder head screws and remove head with exhaust manifold attached. *If left head is being removed, it will be necessary to raise head off dowel pins, move it forward and shift it in order to clear the defroster, power steering and power brake equipment.*

Fig. 2 Cylinder head tightening sequence. 318, 360, 426, 503 engines

Installation

Right and left heads are the same except for the location of the water passage plug in end of water passage. Therefore, only one head is provided for service replacement. New heads are complete with valve guides, rocker arm studs and all plugs except the one water passage plug.

When installing a new head, ream the valve guides and check the concentricity of valves seats. Transfer all serviceable parts to the new head, using new seals on the intake valve stems and new exhaust manifold gasket. Install new water passage plug using gasket cement, and install new intake manifold mounting studs.

Install the head in the reverse order of removal. The head screws are three different lengths. When inserted in the proper holes all screws will project an equal distance from the head. Do not use sealer of any kind on the threads. Tighten screws evenly to 90-95 lb. ft. torque.

Use four thin (.075") gaskets or two thick (.135") gaskets when installing the exhaust crossover pipe to the exhaust manifold.

V8-324 & 370 Engines

To remove either or both cylinder heads, proceed as follows:

1. Drain cooling system and disconnect upper radiator hose from water outlet.
2. Remove air cleaner and generator.
3. Remove spark plug wires.
4. Disconnect throttle linkage.
5. Disconnect spark plug wire and air cleaner supports from cylinder heads.
6. Remove distributor cap and lift cap and high tension wire assembly with supports from engine.
7. Remove fuel pump-to-carburetor fuel line and two vacuum lines from carburetor to fuel pump and distributor.

8. Remove valve covers.
9. Remove intake manifold with coil and carburetor attached.
10. Disconnect exhaust pipe from exhaust manifold.
11. Remove rocker arm shaft with rocker arms and brackets.
12. Before removing push rods, rock rods to break oil seal between rod and lifter to avoid pulling lifter from bore. Then remove rods and place them in a rack with numbered holes to assure installation in their original position.
13. Remove cylinder head with exhaust manifold attached.

Installation

Coat a new gasket on both sides with No. 3 gasket sealer and install the gasket with the crimped side up.

After cylinder heads have been placed in position, the push rods and rocker arm assemblies should be installed and care taken to see that the push rods are properly seated in the rocker arms and valve lifters.

Cylinder head bolts should be tightened in the sequence shown in Fig. 4 and to 65 to 70 lbs. ft. torque.

Valve cover gaskets should be cemented to the valve cover by coating the valve cover on one side with high compression gasket cement or gasket shellac.

New intake manifold gaskets coated

on both sides with No. 3 sealer must always be used when intake manifold is replaced. Threads of the manifold bolts should be dipped in No. 3 sealer before installing. Manifold attaching bolts and nuts should then be tightened in a criss-cross fashion to 22-66 lbs. ft. torque. It is very important that the intake manifold be properly centered between cylinder heads before bolts are tightened.

ROCKER ARM SERVICE

V6 and V12 Engines

Referring to Fig. 5A, assemble rocker arms, springs and brackets on rocker arm shaft, then install end brackets. Lubricate all moving parts with engine oil.

Place steel washer on each bracket bolt, then locate rocker arm shaft and bracket assembly on cylinder head and start bracket bolts into tapped holes. Back off adjusting screws, then tighten bracket bolts evenly while holding adjusting screws in respective push rod sockets. *Use special bolt at position (1) (Fig. 5A) to assure correct position of shaft (6).*

Tighten cylinder head to specified torque and then adjust valve clearance.

228, 248, 270 Engines

When disassembled, examine each rocker arm assembly for damage at threads and for distortion. Measure the inside diameter of the rocker arm bores and compare with new dimensions shown in Fig. 5. If worn in excess of .008″, install new rocker arms, Fig. 6.

Examine push rods for distortion. Also check radius at lower end and socket at upper end of each push rod for evidence of roughness. Replace with new parts if damaged in any way.

Check the fit of the valve lifters in recesses in crankcase. The diameter of the lifter bore is .9905-.9915″; if the bore is worn in excess of .002″, an oversize lifter should be installed. The diameter of a new lifter is .989-.990″; if worn in excess of .002″, install new lifter.

302 Engine

Inspect rocker arms, shafts, brackets, push rods and valve lifters as outlined for smaller size engines above. However, rocker arms are fitted with bushings which, if worn in excess of .008″, may be pressed out and new bushings pressed in, Fig. 7. Ream bushings to the dimension shown after installation.

360, 426, 503 Engines

Inspect rocker arms, shafts, brackets, push rods and valve lifters as outlined for the smaller engines. Rocker arms are fitted with bushings that are diamond bored to close tolerances and when worn the complete rocker arm should be replaced.

Rocker arm bushing inside diameter is .874-.875″. Rocker shaft diameter is .8725-.8735″.

Refer to Fig. 8 as a guide when assembling rocker arm mechanism.

Rocker arm should be replaced if the valve stem contact surface is worn or if other damage is found.

Make sure the shaft is clean and that oil holes are not plugged. If an excessive amount of foreign material inside of shaft is indicated, drill and tap the oil plug in each end of shaft, thread a puller screw into the plugs and pull the plugs from the shaft to permit thorough cleaning.

Check the shaft for scoring or wear at the point of rocker arm contact. Diameter of shaft is .791-.792″; if worn in excess of .005″, replace shaft.

If the oil plugs were removed from the ends of shaft and shaft is being reused, press in new oil plugs to a depth of at least ¼″ from end of shaft.

Examine each rocker arm shaft bracket for distortion. Check for stripped threads in top of No. 1 shaft bracket. Replace brackets if damaged in any way.

Fig. 10 Left cylinder head (left front view). V8-288, 316, 336, 347 engines

V8-288 Engine

When the head is disassembled, clean the rocker arms and balls and look for evidence of wear. Clean the push rods and oil passage through center of each rod. See that the rods are straight.

Check oil passages from oil gallery to rocker arm studs. A simple test can be made by using a rubber hose and smoke. Block the lower end of the cylinder head screw hole which feeds the oil gallery, Figs. 9 and 10, and blow smoke in the top end of the hole through the rubber hose. Smoke should come out of the hole in each stud.

Rocker arm studs are replaceable providing a press of two tons capacity or more is available.

1. Remove cylinder head.
2. Remove rocker arm.
3. Pull out rocker arm stud by using washers or other suitable shims under the nut.
4. Ream out hole, Fig. 11. *Service replacement studs are .003" oversize.*
5. Remove plugs from ends of cylinder head oil gallery and thoroughly clean out metal deposits and foreign matter from oil gallery.
6. Position rocker arm on new stud and place Stud Installer J-5716, Fig. 12, on stud in place of rocker arm ball.
7. Coat stud with white lead and oil, and with cylinder head mounted in press on Tool No. J-5712 so studs are vertical, position new stud with rocker arm and stud installer over hole in head, Fig. 12.
8. Press stud into head until it is in about halfway ($\frac{7}{16}$").
9. Position Valve Train Gauge J-5710, Fig. 13, in push rod hole so that it seats properly in rocker arm.
10. With valve seated, slowly press stud into cylinder head until the gauge is positioned as shown in Fig. 13.
11. Blow air through hole in stud to be sure passage is not restricted.
12. Reinstall parts removed and install head.

Fig. 9 Left cylinder head (right rear view). V8-288, 316, 336, 347 engines

V8-316, 336, 347 Engines

No valve adjustment is required on these engines due to the new valve train. This was accomplished by moving the valve lifter oil supply hole nearer the top of the lifter body to insure ample oil reserve, along with the new design of the rocker arm ball retaining nut and rocker arm mounting stud.

V8-324 & 370 Engines

Rocker arms are identical except that the intake arms may be identified by a brass pin which blocks the upper end of the drilled passage leading to the push rod oil hole. The oil passage provides lubrication between the push rod and its seat in the rocker arm.

The rocker shafts are supported by four brackets on each cylinder head, three of which are identical. The remaining bracket on each head has an oil hole drilled through the bottom which indexes with the oil line in the cylinder head originating at the No. 2 camshaft bearing for the left side and No. 4 camshaft bearing on the right side. These two brackets can be identified by their dowel pins which position the rocker arm shaft with respect to the oil passages.

Three rocker shaft springs are used to keep the center rocker arms in proper position against the brackets, whereas both end rocker arms are positioned by a flat washer, wave washer and a cotter pin, Fig. 14.

When necessary to disassemble the rocker arm shaft assembly, remove the cotter pin, wave washer and flat washer. Remove rocker arms, supports and springs from shaft. Note that one support is doweled to each shaft and should not be removed when disassembling the shaft assembly.

When assembling rocker arms and supports to shaft, be sure the supports are installed correctly on the shaft in relation to the doweled support. Be sure also, that the rocker arm (push rod end) is on the same side as the large cylinder head bolt hole in each support.

VALVES, ADJUST

Six-Cyl. Engines

Whenever the cylinder head has been tightened or after the engine has been rebuilt, the valve lash should be set to the specifications given in the chart. Adjust the lash with the engine at operating temperature and idling slowly.

Fig. 11 Reaming rocker arm stud hole. V8-288, 316, 336, 347 engines

Fig. 12 Pressing in new rocker arm stud. V8-288, 316, 336, 347 engines

Fig. 14 Rocker arm assembly. V8-324 engine

V8-288 Engines

Whenever rocker arms, push rods and valve lifters are removed, an initial setting of the rocker arm nuts must be made to establish the correct operation of the valve train.

Install the lifters in the bores from which they were removed. Install push rods and rocker arms with balls and start rocker arm nuts. *Push rods should be installed in same places they were originally installed and with same end contacting rocker arm.*

The self-locking rocker arm nuts should be adjusted as follows to properly position the plungers within the lifters. Each rocker arm nut must be adjusted when the corresponding valve is completely closed. The simplest and most accurate way to make this adjustment is to adjust one cylinder at a time while it is in the firing position.

With distributor rotor pointing to firing position for No. 1 cylinder, tighten No. 1 intake and exhaust rocker arm ball nuts, one at a time, just until there is no up and down movement of the push rod (do not depress lifter plunger). When rocker arm movement has just been eliminated, tighten rocker arm ball nut *one complete turn.* This will depress the plunger the proper amount within the lifter.

Turn the crankshaft and adjust each set of rocker arm nuts according to the firing order of the engine in the same manner as outlined above.

V8-316, 336, 347 Engines

To install a new rocker arm stud in the cylinder head, a new Rocker Arm Stud Installer J-6301 and a new Valve Train Gauge J-6324 should be used, following the procedure outlined for V8-288 engines.

When the valve rocker arm ball retaining nut is tightened to a torque of 15 lbs. ft., proper location of the rocker arm with respect to the push rod and valve lifter is automatically assured. The need for adjusting rocker arm position as in the V8-288 engine is thereby eliminated.

Fig. 13 Gauge should be positioned as shown when stud is properly installed. V8-288, 316, 336, 347 engines

VALVES, REMOVE

In Line Six-Cyl. Engines

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

V6 and V12 Engines

Referring to Figs. 14A and 14B, use valve spring compressor to relieve pressure of valve springs against retaining parts. Remove valve keys and release spring compressor, then remove valves and related parts.

On 305A light duty engines remove valve spring seats from counterbore in cylinder head. On 305B, 305C and larger engines remove valve rotators from counterbores in cylinder head.

VALVE ADJUSTING INSTRUCTIONS

702-ENGINES

1. Turn crankshaft so No. 9 cam lobe is up (intake valve open on No. 5 cylinder) and UDC#1 mark on crankshaft pulley is aligned with pointer. At rocker arms No. 1, 3, 5, 6, 8, 10, 11, 14, 15, 19, 22, and 24 turn adjusting screw down until there is no slack in push rod, then continue to tighten adjusting screw 1 ¼ turns.
2. Turn crankshaft 360° so No. 15 cam lobe is up (intake valve open on No. 7 cylinder) and UDC#1 mark on crankshaft pulley is aligned with pointer. Adjust rocker arms No. 2, 4, 7, 9, 12, 13, 16, 17, 18, 20, 21, and 23 in same manner described in step 1 above.

NOTE: Lifters must be full of oil before adjusting. Refer to lifter assembling and testing instructions in text. Rocker arm numbering corresponds to cam lobe positions running consecutively from front to rear of engine.

Fig. 14C Adjusting hydraulic valve lifters on V12 engines

Warning: All engines except 305 have sodium cooled type valves. Sodium cooled valves must not be discarded with other scrap metal. If one of these valves is accidentally broken the sodium will react violently with water resulting in fire or explosion due to chemical action. Serious burns will result if sodium or its oxide comes in contact with the skin.

V8-288, 316, 336, 347 Engines

Remove valve spring retainer cup locks (keepers), intake valve stem oil seals, valve spring retainer cups, valve springs and valves, using valve spring compressor J-5712.

Intake valve stem oil seals must be discarded and replaced with new seals anytime they are removed.

Place valves in a valve train holding stand or in a board with numbered holes so the valves may be replaced in the exact port from which they were removed.

V8-324 & 370 Engines

To remove the valve springs and dampers, take off the cylinder head as outlined previously. Then use a suitable valve spring compressor, like the one shown in Fig. 15, compress the valve springs until the valve stem locks can be removed. Remove spring retainer, spring and dampers.

Fig. 15 Showing tool to remove and replace valves and springs. V8-324 engine

VALVES, GRIND

V6 and V12 Engines

Care must be taken when grinding valves not to remove too much stock from the valve face. If it should be necessary to reduce thickness of intake valve head to $\frac{1}{64}$" or less at outer edge of valve head to obtain a smooth face, discard the valve. Exhaust valves should not be used if the outer edge of the valve head is less than $\frac{3}{64}$" after refacing.

V8-324, V8-370 & In Line Six-Cyl. Engines

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. This condition leads to premature breakage, burning and pre-ignition due to heat localizing on this knife edge. If the edge of the valve head is less than $\frac{1}{32}$" thick after grinding, replace the valve.

Inspect the valve seats in the head for cracks, burns, pits, ridges or improper angle. Reconditioning the valve seats is very important because the seating of the valves must be perfect for the engine to deliver the power and performance built into it. Another important factor is the cooling of the valve heads. Good contact between each valve and its seat

Fig. 16 Checking concentricity of valve seat with dial gauge

in the head is imperative to insure that the heat in the valve head will be properly carried away.

Regardless of the methods for valve seat reconditioning, the final seat for the valves should be $\frac{3}{64}''$ to $\frac{1}{16}''$ for intake seats and $\frac{1}{16}''$ to $\frac{3}{32}''$ for exhaust seats. Seats should be concentric within .002″ as indicated on a dial gauge, Fig. 16.

Caution: 360, 426, 503 Engines

Exhaust valves in these engines are filled with sodium as a cooling agent. These valves must not be discarded with other scrap metal. If a sodium cooled valve is accidentally broken, the sodium will react violently with water, resulting in fire and explosion due to chemical action. Serious burns will result if sodium or its oxide comes in contact with the skin.

V8-288, 316, 336, 347 Engines

Intake valve seat angle is 30°, exhaust seat angle is 45°. The intake face angle is 29° and exhaust valve face angle is 44°. This will provide hairline contact to provide positive sealing and reduce build-up of deposits on seating surfaces.

Do not use refacing equipment excessively; only enough material should be removed to true up surfaces and remove pits. The valve head will run hotter as its thickness is diminished; therefore, if the valve face cannot be cleaned up without grinding to a point where the outside diameter of the valve head has a sharp edge, the valve should be replaced. Whenever it is necessary to replace a valve, the new valve should be of the same stem diameter as the valve removed (unless the guide is replaced also).

Width of exhaust valve seats should be a very accurate $\frac{1}{16}''$. Intake valve seat should be between $\frac{3}{64}''$ and a liberal $\frac{1}{16}''$. If seat width is excessive it should be narrowed by grinding with a flat stone, Fig. 17. This is the only method that should be used to narrow the seat. Lapping of valve seats is not required or recommended.

Concentricity of valve seat and valve guide can be checked by using a suitable dial indicator or prussian blue. When using a dial indicator, total runout should not exceed .001″.

When prussian blue is used, a light coat should be applied to the face of the valve only and the valve rotated in its seat. If blue appears all the way around the valve seat, the valve seat and valve guide are concentric with one another.

Check concentricity of valve stem and face of valve. After cleaning prussian blue from valve seat from preceding check, lightly coat valve seat with prussian blue and rotate valve in guide. If blue appears all the way around the valve, the valve stem and valve face are concentric with one another.

To check and correct the length of the valve stem, position the rocker arm on the stud and hold in place with Rocker Arm Stud Installer J-5716, Fig. 18. Slip the valve into place and hold it against the valve seat. While holding the rocker arm and valve in position securely, insert Valve Train Gauge J-5710, Fig. 18, through push rod hole and seat snugly in push rod seat of rocker arm. With all parts seated, step end of gauge should be at least flush with gasket face of head, but should not project past the step on the gauge, as shown in Fig. 18.

If the gauge projects too far, indicating that the valve stem is too long, grind the tip of the valve stem as necessary to make the gauge index properly. *Do not overheat the valve stem when grinding as excessive heat will soften the hardened stem, causing rapid wear.*

VALVE ROTATORS

All Engines (Except 228, V6-305 & Light Duty 288)

The parts involved in the rotating mechanism, Fig. 19, are a special spring seat retainer, a pair of flat half-moon keys, a close fitting cap located on the valve stem and a specially constructed valve stem.

In order to accomodate valve expansion, the valve lash must be maintained. When camshaft rotation causes this lash or clearance to be taken up, the cap on the valve stem causes the valve keys to raise the spring retainer, removing the load on the valve springs from the valve *before* the valve is moved from its seat. A clearance of .002-.004″ should be maintained between the end face of the valve stem and cap. This is the distance the spring retainer is moved *before* the valve is moved. The slow valve rotating motion is caused by the vibration of the valve, the flowing of exhaust gases around the valve head, and a slight rotating motion imparted to the valve by the valve spring.

Fig. 17 Valve seat after grinding with flat stone. V8-288, 316, 336, 347 engines

Fig. 18 Checking length of valve stem. V8-288, 316, 336, 347 engines

Whenever valve work is being done, a check for clearance should be made by holding the assembled valve and rotating mechanism in the hands. With one hand, press down on the valve cap and turn the valve with the other hand. If the valve turns readily, it indicates that there is clearance present.

A special gauge is available to check this clearance. If the gauge indicates no clearance, grind off the end of the valve stem. If the clearance is too great, grind off the open end of the valve cap.

VALVE SEAT INSERTS

6-318, 360, 426, 503, V6 and V12 Engines

Figs. 20 and 20A illustrate the special tools which are available to remove and install these inserts. Lacking these tools, an alternate method is to drill two holes at opposite sides of the insert but not all the way through. Then cut through the undrilled portion with a sharp chisel and remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the insert with dry ice to obtain maximum contraction of the metal. It may also be necessary to heat the cylinder head by immersing in water heated to 180-200 degrees. Then with the insert chilled and the head heated, quickly drive the insert in place, being sure to start it in square.

EXHAUST VALVE WATER NOZZLES

In Line Six-Cyl. Engines

Exhaust valve seats are effectively cooled by a constant spray of water un-

Fig. 19 Valve rotator and retaining parts. Six-cyl. engines. Typical of V8s

Fig. 21 Water nozzle installation. 228, 248, 270, 302 engines

Fig. 22 Water nozzle installation. 318, 360, 426, 503 engines

der pressure from nozzles in the cylinder head. These copper nozzles are installed in the head in such a manner that the opening near the upper end directs the flow of water to the valve seat. If nozzles are removed, great care should be taken to see that the opening is pointed in the proper direction, and that the nozzles are of the proper length.

Examine nozzles for evidence of scale formations and for disintegration. If scale cannot be removed without damaging nozzles, they must be replaced. To remove a nozzle, collapse its edge with a sharp chisel and pull it out of the cylinder head.

When installing new nozzles, aligning the contour of the nozzle with the hole in the cylinder head will position the nozzles with the openings pointing in the proper direction. Refer to Figs. 21 and 22 to identify the length and type of nozzles to be installed in each opening. Nozzles must be pressed in flush with the face of the cylinder head.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 22A. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if

Fig. 22A Checking installed height of valve spring

shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is $\frac{1}{16}$", and since the acceptable valve head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

All Engines

Wash all springs with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 23, and according to the specifications given in the *Tune Up and Valve Specifications* chart. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

VALVE GUIDES

V6 and V12 Engines

Valve guides in these engines are an integral part of the head and, therefore, cannot be removed. For service, guide holes can be reamed oversize to accommodate one of several service valves with oversize stems. Intake valves are available with .005" and .010" oversize stems. Exhaust valves are available with oversize stems of .005", .010" and .020". For 351 and larger engines a .030" oversize valve is also available.

Select the reamer for the smallest oversize which will provide a clean straight bore through the valve guide. After reaming a new seat should be cut into the head to assure perfect seating of the new valve.

In Line Six-Cyl. Engines

Valve guides furnished for service replacement are designed to give proper clearance when pressed into the cylinder head without reaming, if the proper tools are used for the installation operation. Be sure valve stems are free in the new guides before installing valve springs.

On 228, 248, 270 and 302 engines, when installed, exhaust guides must protrude $\frac{55}{64}$" from head; intake guides $\frac{59}{64}$". These

Fig. 20 Removing exhaust valve seat insert. V6 and V12 engines

Fig. 20A Installing exhaust valve seat insert. V6 and V12 engines

dimensions are subject to a tolerance of plus 0 and minus $\frac{1}{32}''$.

On 318, 360, 426 and 503 engines, press in the new guides until the shoulder on the guide is flush with the edge of the recess in the cylinder head.

V8-288 Engine

1. Drive out old valve guide, Fig. 24.
2. Drive new valve guide into place from combustion side of cylinder head as follows:
3. Coat outside of valve guide with white lead and oil.
4. Start chamfered end of guide into its hole and drive into cylinder head with the tool shown in Fig. 24 until the end of the guide is positioned as shown in Fig. 25. Use the depth gauge shown in Fig. 26 to measure this distance.

Since valve guides taper .0015″ per inch, a tapered reamer, Fig. 27, must be used to ream the guides to provide the correct taper and correct valve fit. Correct fit of valve stem in guide is such that when valve is started in guide it will just drop through of its own weight, but will have no perceptible side play.

Since this is a tapered reamer, the hole in the valve guide will become larger as the reamer is turned down. To avoid reaming oversize, when using the type reamer shown in Fig. 27, set the sliding stop to 3¼″ from the end and ream until the sliding stop bottoms. Then, move the stop back to 3½″ from the end and carefully continue reaming a little at a time, alternately reaming and testing the valves stem fit until the exact fit is obtained.

V8-316 Engine

Valve guides are cast integral with the cylinder head and are tapered as in the past. Some cylinder heads may be equipped with one or more of the removable type guides. These guides are installed in production if the integral valve guides are reamed oversize in the machining operation.

If necessary to service a guide to accommodate either the .001″ or .003″

Fig. 23 Checking valve spring tension with a spring testing fixture and torque wrench

Fig. 24 Driving out valve guide. V8-288 engine

Fig. 25 Correct installation of valve guide. V8-288 engines

oversize valve stem, use the proper reamer, Fig. 27. If replacement of a removable type valve guide is necessary, use the procedure outlined previously for V8-288 engines.

V8-336 & 347 Engines

Unlike previous models, the valve guides are straight (not tapered). Valves with oversize stems are available in .001″, .003″ and .005″ oversize. When reaming guides a clearance of .0015-.0025″ for intake and .0024-.0039″ for exhaust must be maintained. For best results when installing .005″ stem use a .003″ oversize reamer first and then ream to .005″ oversize. *Always reface the valve and valve seat after reaming valve guide.*

V8-324 & 370 Engines

The overall length of the intake and exhaust valve guides is the same. But

the intake guide has a smaller bore than the exhaust guide and is also beveled at the bottom.

Both intake and exhaust valve guides extend $\frac{27}{32}$ in. above the face of the valve spring seat. It is important when installing a valve guide that the distance from the top of the guide to the cylinder head be held to the above specifications. Therefore, tool BT-13 is available to make this installation properly. With this tool or its equivalent, drive the new guide in from the top of the cylinder head until the tool seats on the valve spring seat.

VALVE LIFTERS

V6 and V12 Engines

Hydraulic valve lifters are used in V12 engines whereas mechanical lifters are employed in V6's. It is not necessary to remove the cylinder head to remove and install valve lifters if a suitable magnet rod or an expansion type tool is available, Fig. 27A, which is designed to remove and install the lifters through holes in cylinder head.

Removal, V8-288, 316, 336, 347 Engines

Remove intake manifold, push rod cover and rocker arm cover. Loosen rocker arm ball nut and move rocker arm off push rod.

Before removing lifter that is suspected of having a stuck plunger, it can be tested by using Lifter Plunger Unloader J-5097. To check lifter, Fig. 28, insert pin of unloader tool through hole in push rod seat and push down on tool. Pin will unseat ball and tool will move push rod seat and plunger down. If lifter plunger is stuck, it will be impossible to move push rod seat down. Remove push rod and lifter. If more than one lifter is to be replaced, be sure to identify them (push rods as well) so they will be installed in the same position.

Removal, V8-324 & 370 Engines

To remove valve lifters, take off successively the intake manifold, engine push rod cover, valve cover, rocker arm shaft assembly, push rods and remove valve lifters, Fig. 29.

Valve lifters in production engines may be one of four sizes: standard, .001, .002 or .003 in. oversize. It is important when replacing one or more lifters that the proper size lifter be ordered. An identification numeral is etched on all lifter bodies except standard. The cylinder block is marked for lifter size on the rail under the push rod cover. Valve lifters .005 in. oversize are available for service replacement.

Service

Failure of a hydraulic lifter is generally caused by an inadequate oil supply, dirt or other foreign substance. An air leak at the intake side of the oil pump or too much oil in the engine will cause air bubbles in the oil supply to the lifters, causing them to collapse. This is a probable cause of trouble if several lifters fail to function, but air in the oil is an unlikely cause of failure of a single unit.

Fig. 26 Checking position of valve guide with depth gauge. V8-288 engines

Fig. 27 Reaming valve guide with tapered reamer (tapers .0015" per inch). V8-288, 316, 336, 347 engines

Fig. 27A Removing or installing valve lifter with expansion type tool on V6 and V12 engines

Fig. 28 Layout of hydraulic valve lifter parts. V8-288, 316, 336, 347 engines

In servicing the lifters particular attention should be given the plunger and ball. The plunger should be checked for signs of scoring or wear, and the ball for pitting. Check the ball seat in the end of the plunger for any condition that would not allow the ball to seat perfectly. If any of the above conditions are apparent, install a new lifter assembly.

Do not disassemble a lifter in dirty surroundings or on a dirty work bench. Use clean paper on the bench and, after the lifter has been disassembled, place the loose parts in a numbered rack with the parts of each unit together. Then submerge in clean kerosene as a protection against dirt or corrosion.

With more than one lifter disassembled it is imperative to keep the parts of each lifter separate. The plunger and ball must always be fitted in the same body.

Disassemble

With a suitable tool, pry out the plunger retainer ring. Clean varnish deposits from inside the lifter body above the push rod seat. Then invert the lifter body and drop out the parts.

Cleaning

Wash all lifters in a suitable solvent that will remove all trace of varnish and carbon (paint thinner will do). Then, working on one lifter at a time and using clean lint-free cloths, thoroughly wipe off all parts. Clean the plunger and the internal and external surfaces of the body with a hard wiping action to remove any varnish residue.

To insure absolute cleanliness of a reconditioned lifter assembly, it is ad-

Fig. 29 Hydraulic valve lifter. V8-324 & 370 engines

visable to service one at a time, assembling it before working on the next one.

Inspection

Inspect the lifter body for blow holes and scoring. Replace entire unit if body is roughly scored or grooved.

Using a magnifying glass, inspect the check ball seat for defects. Inspect the outer surface of the plunger for scratches or scores. Defects in the check ball seat or scores or scratches on the outer surface of the plunger which can be felt with the fingernail are causes for replacing the entire unit.

Replace the push rod seat if the area where the push rod contacts is rough or otherwise damaged.

Using a magnifying glass, carefully examine the check ball for nicks, imbedded material or other defects which would prevent proper seating. Even though no defects are found it is advisable to discard the old ball and use a new one when servicing a lifter.

Replace the ball retainer if it is cracked or has a heavily pounded area between the two holes. A small bright spot where the ball contacts the retainer is the normal condition.

Replace the plunger spring only if it is distorted or damaged.

Assemble

Rinse all parts in clean kerosene and assemble without drying. This will avoid the adherence of dust or lint if they are blown off or wiped with cloth.

Place the parts in the body. The plunger must slide freely in the body. Place the push rod seat on the plunger and depress these parts and install the plunger retainer in the groove in the body.

Installation

Install lifters in the reverse order of removal and, on 288 engines, be sure to adjust the rocker arm nuts as directed under *Valves, Adjust.*

TIMING GEAR COVER

V6 and V12 Engines

To remove cover, block crankshaft and remove retaining bolt and washer at front side of crankshaft pulley. Assemble a suitable puller and remove pulley. Remove bolts attaching front cover to cylinder block and jar cover loose with a lead hammer.

In-Line Six-Cyl. Engines

To gain access to the timing gears, the oil pan and crankshaft pulley must be removed and the timing gear cover taken off the engine. Bend the lock away from the bolts at the crankshaft front bearing cap and remove the two bolts and copper washers. These bolts are threaded into the tapped plate welded to the timing gear cover. Remove the screws at the front side of the cover and remove the cover and gasket.

Removal, V8-288, 316, 336, 347 Engines

1. Drain radiator.
2. On vehicles with power steering, remove pump with mounting bracket from pad on top of timing chain cover and lay back on fender skirt where it will be out of the way. Before doing so, however, disconnect battery ground strap to prevent pump from grounding "BAT" terminal of regulator.
3. Remove generator.
4. Remove fan belt and power steering pump belt.
5. Remove fan and pulley.
6. Disconnect upper radiator hose from radiator and remove fan shroud.
7. Disconnect lower radiator hose and heater hose and take off radiator.
8. Remove water inlet elbows from cylinder heads (leave attached to hose).
9. Remove fuel pump.
10. Remove harmonic balancer.
11. Take weight off engine front insulator, using suitable engine lifting equipment. *Do not use jack under engine oil pan.*
12. Unfasten front engine support from timing chain cover.
13. Remove front four oil pan to timing chain cover screws.
14. Unfasten timing chain cover from block and remove cover.

Fig. 30 Front of engine with timing chain cover removed. V8-288, 316, 336, 347 engines

Fig. 30A Timing gears showing timing marks on V6-401, 478, V12-702 engines

Fig. 31 Location of marks on timing gears. 228, 248, 270, 302 engines

Installation

If a new front oil pan gasket is needed, cement it to the pan. Install new cover seal, Fig. 30, coating seal with graphite lubricant. If a new fuel pump eccentric is to be installed, remove camshaft sprocket retaining screw and washer and remove eccentric. Install new eccentric, indexing pin on eccentric with hole in camshaft sprocket. Insert retainer screw with washer and tighten securely.

After installing the cover, install the four oil pan screws and tighten to 10-12 lb. ft. torque. Loosely install front engine support-to-chain cover screws. Then lower engine and tighten screws to 60 lb. ft. torque.

Complete the balance of the work in the reverse order of removal.

V6-401, 478, V12-702

To remove the cover, drain the cooling system and disconnect lower radiator hose. Disconnect external water by-pass at the intake manifold. Drop the oil pan. Take off radiator, shroud, fan blades, pulleys, vibration damper and fuel pump. Unfasten the cover from the block and lift it off.

TIMING GEARS

V6-401, 478, V12-702

For correct valve timing, the "X" marks on the camshaft and idler gears should be aligned, Fig. 30A, and the "O" marks on the idler and crankshaft gears should be aligned.

228, 248, 270, 302 Engines

For correct valve timing, the marks on the camshaft and crankshaft gear should be matched. If the timing marks are not legible, refer to Fig. 31 for

method of scribing and marking gears with correct timing mark.

The camshaft, together with the gear and thrust plate is removed from the engine as an assembly. When removed, inspect the face of the thrust plate for wear. With a feeler gauge, check the clearance between the hub of the gear and thrust plate, Fig. 32. If the plate is worn or grooved excessively, it should be replaced. As a general rule, a new thrust plate should be used at assembly.

After both timing gears have been installed, check the backlash with a narrow feeler gauge. Correct backlash is .003-.004" when new gears are used. Turn the crankshaft and check the backlash at several points. Specified backlash must exist at all points.

318, 360, 426, 503 Engines

For correct valve timing on these engines, the marks on the camshaft and crankshaft gears should match. If the timing marks are not legible, refer to Figs. 33 and 34 for method of scribing and marking gears with correct timing mark.

If the camshaft is out of the engine, an arbor press may be used to install the timing gear. The tool shown in Fig. 35 should be used to install the gears if the camshaft is in the engine. In either case, install the thrust plate over the end of the camshaft with the part number and trade mark away from the gear. Drive a new key in the camshaft keyway. With the timing mark on the gear facing away from the camshaft, force the gear on the shaft until the hub contacts the front bearing journal shoulder. Check the clearance between the thrust plate and the cheek at the bearing journal with a feeler gauge. Clearance should be .003-.007".

After both gears are installed, check the backlash with a feeler gauge at several points. Backlash with new gears should be .0015-.0035".

TIMING CHAIN

V6-305, V6-351

When chain is properly installed, a straightedge aligned with the center of the crankshaft and camshaft will also be aligned with the timing marks as shown in Fig. 36A. Install fuel pump eccentric at front side of camshaft sprocket. Special washer and bolt (1 and 12, Fig. 36A) are used to retain eccentric and sprocket. Tighten bolt to a torque of 60-70 ft lbs.

V8-288, 316, 336, 347 Engines

To remove the chain, take off radiator and timing chain cover as outlined above. Remove fuel pump eccentric and cover oil seal. Align timing marks, Fig. 36, to simplify proper positioning of sprockets during reassembly. Slide chain and sprockets off ends of camshaft and crankshaft.

Install timing chain and/or sprockets, making sure timing marks on sprockets are aligned exactly on a straight line passing through the shaft centers. Then replace other parts removed.

Fig. 32 Checking clearance between camshaft hub and thrust plate. 228, 248, 270, 302 engines

Fig. 33 Location of timing marks. 318, 360 engines

Fig. 34 Location of timing marks. 426, 503 engines

V8-324 & 370 Engines

Remove the chain cover as outlined previously and take off the chain and sprockets as follows: Slide the oil slinger off the front end of the crankshaft. Remove the fuel pump eccentric from the front of the camshaft sprocket. Take off the chain and sprockets.

To assemble, place the chain over the sprockets so that when the camshaft

Fig. 35 Installing timing gears. 318, 360, 426, 503 engines

Fig. 36 Valve timing marks. V8-288, 316, 336, 347 engines

sprocket and fuel pump eccentric are bolted to the camshaft hub, the timing marks on both sprockets are facing each other in line with the center of both the camshaft and crankshaft, Fig. 37. The fuel pump eccentric must be assembled with the machined step against the sprocket.

CAMSHAFT & BEARINGS

V6 and V12 Engines

Camshaft is supported on bushing type bearings and all journals are pressure lubricated. An oil trough just below camshaft holds oil into which the cam lobes dip as the camshaft rotates.

To remove the camshaft, remove thrust plate attaching bolts at front end of camshaft. Pull camshaft forward to remove from cylinder block. Remove key from keyway in camshaft, then remove thrust plate and gear spacer.

To install camshaft, apply engine oil to camshaft journals and cam lobes, then install camshaft in block. If spacer has been removed, install spacer with chamfer toward bearing journal and drive key into keyway. Install camshaft thrust plate. Sprocket is installed together with chain.

228, 248, 270, 302 Engines

Four steel-backed, babbitt-lined bearings pressed into the bores of the crankcase support the camshaft. When necessary to install new bearings, be sure the oil holes in the bearings are in line with the holes in the block.

After bearings are installed, lock each bearing by staking it in place with a 9/32" round nose drift through the oil passages between the crankshaft bearings and camshaft bearings, Fig. 38. Holes are provided into which each bearing must be staked to prevent loosening.

Ream camshaft bearings to provide a clearance of .001-.003". After the reaming operation, clean bearings thoroughly, using special care to see that oil holes are clear and free of cuttings.

318, 360, 426, 503 Engines

The camshaft is supported in four bronze bearings which are reamed to size after installation in the crankcase.

If inspection shows that camshaft bearings are loose, worn or burned, bearings must be removed and a new set installed. Mark the position of the oil hole on the front face of each camshaft bearing bore, Fig. 39. This is necessary in order to assure proper alignment of the oil hole in the bearing and oil hole in bearing bore. After bearings are installed, they must be reamed to provide a clearance of .002-.0035".

V8-288, 316, 336, 347 Engines

Removal

1. Drain radiator.
2. Remove intake manifold.
3. Remove crankcase ventilator outlet pipe.
4. Remove push rod cover.
5. Disconnect spark plug wires from plugs.
6. Remove rocker arm covers.
7. Loosen rocker arm ball nuts so that rocker arms can be disengaged from push rods and turned sideways.
8. Remove push rods and hydraulic lifters.
9. Remove timing chain cover, chain, sprockets and related parts.
10. Unfasten and remove camshaft thrust plate.
11. Slide camshaft out of engine carefully, making sure not to damage bearings in block.

Installation

Reverse the removal procedure to install the camshaft. Line up the timing marks on the sprockets and install the chain as shown in Fig. 36. Be sure to adjust the rocker arm ball nuts as outlined under *Valves, Adjust*.

V8-324 & 370 Engines

A thrust plunger and spring is used to control end play of the camshaft. The plunger contacts a pad located on the engine front cover. Two threaded plugs are also added to seal the oil passages.

1 Bolt
2 Cap
3 Thrust Plate Screw
4 Dowel Hole
5 Fuel Pump Eccentric
6 Timing Chain
7 Pulley Hub Key
8 Crankshaft
9 Crankshaft Sprocket
10 Timing Marks
11 Camshaft Sprocket
12 Eccentric Clamp Washer (Special)

Fig. 36A Timing chain and sprocket details. V6-305 and V6-351 engines

Fig. 37 Valve timing for No. 6 cylinder. V8-324 & 370 engines

Fig. 38 Locking camshaft bearings in place with punch 228, 248, 270, 302 engines

A small hole is provided in one of the threaded plugs to lubricate the fuel pump eccentric and timing chain.

All camshaft bearings are replaceable, and if clearance is excessive, new bearings may be pressed in place after the camshaft and old bearings have been removed.

Before installing new bearings, see that the oil feed holes are clean and free from sludge and other foreign particles; and when replacing bearings, be sure to line up the holes in the bearings with those of the crankcase to assure adequate lubrication.

Fig. 39 Showing oil holes in camshaft bearings aligned with oil passages in crankcase. 308, 318, 360, 426, 477, 503 engines

Fig. 40 Assemble piston to rod as shown. 318, 360, 426, 503 engines

Fig. 41 On V8-288 & 316 engines, assemble piston to rod as shown

Fig. 41A Pistons assembled to rods. V8-336, 347 engines

Fig. 41B Pistons assembled to rods. V8-324 engine

Fig. 41C Pistons assembled to rods. V8-370 engine

To remove the camshaft from these engines, proceed successively as follows:

1. Remove radiator and heater hoses.
2. Remove air cleaner.
3. Remove fuel and vacuum lines.
4. Remove distributor.
5. Remove throttle linkage from carburetor.
6. Remove fan, pulleys and belts.
7. Remove generator, belt & brackets.
8. Remove spark plug wire support.
9. Remove external water by-pass tube.
10. Remove push rod covers, rocker arm assembly and push rods.
11. Remove intake manifold.
12. Remove cylinder block cover.
13. Remove valve lifters and place in numbered rack to keep them clean and so they can be replaced in the same location as removed.
14. Remove upper radiator baffle support.
15. Remove radiator core.
16. Remove vibration damper.
17. Remove fuel pump.
18. Remove exhaust cross-over pipe.
19. Remove steering idler arm.
20. Remove oil pan.
21. Remove front engine mounting.
22. Remove timing chain cover.
23. Remove fuel pump eccentric, timing chain and sprocket.
24. Remove camshaft thrust plate and withdraw camshaft.
25. To replace, reverse sequence of operations, set valve timing and adjust carburetor idle.

PISTONS & RODS, REMOVE

All Engines

After removing the cylinder head and oil pan, examine the cylinder bore above the ring travel area. If the bores are worn so that a ridge or shoulder exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. Make sure rods and pistons are properly numbered so they can be reinstalled in their proper cylinders. It is advisable to install the caps on the rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

V6 and V12 Engines

Install piston and rod assembly using care to match the number on the rod and cap. *Numbers for rods on right-hand cylinders must be toward right-hand side of crankcase, while numbers on rods for left-hand cylinders must be toward left-hand side of crankcase.*

228, 248, 270, 302 Engines

Install the pistons in their respective cylinders with numbers on the connecting rods facing the camshaft. When installing the bearing caps to the rods, be sure to have the number on the cap on the same side as the number on the rod.

318, 360, 426, 503 Engines

Insert connecting rod in cylinder bore with the step-head side of piston and drilled oil hole in rod opposite the camshaft side of the cylinder block, Fig. 40.

All V8 Engines

Figs. 41, 41A, 41B and 41C illustrate the correct assembly of pistons to rods.

PISTONS, REPLACE

All Engines

For checking sizes of stock pistons, measurements should be taken with micrometer calipers across the high point of the piston skirt contour, which is across the piston pin support ribs on the piston skirt.

Before any attempt is made to fit new pistons, cylinder bores should be carefully measured, and refinished. Cylinders that are not badly scored but need a "cleaning up" to bring them within satisfactory working limits may be reconditioned with a hone.

A good job should show measurements of not more than .0005" out-of-round or taper. If cylinders are scored badly or out-of-round excessively, they should be bored first with a reliable boring tool and then polished with a hone.

When fitting pistons, use feeler stock of the thickness given in the *Piston & Ring* table. The feeler should be about ½" wide and long enough to extend down into the bore for the full length of the piston. Insert the piston into the bore upside down and place the feeler

stock between the piston and the cylinder wall on the high point of the piston contour. Hook the feeler to a spring scale and withdraw the feeler by pulling it out of the cylinder with the scale. The piston is fitted properly if the amount of pounds pull registered on the scale comes within the limits given in the *Piston & Ring* table.

PISTON RINGS, REPLACE

All Engines

When new piston rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gaps of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with the lower end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

PISTON PINS, REPLACE

V6 and V12 Engines

Piston pins are a floating fit in piston bosses and in the connecting rod bushing. Pins are retained by snap rings installed in a groove in each pin boss.

If a new bushing is installed in connecting rod it should be honed to provide a "thumb push" fit of pin in bushing with parts at normal room temperature of 70 degrees.

In-Line Six-Cyl. Engines

Oversize piston pins of .0015", .0025", .005" and .010" are available for service in case pin bore in piston or connecting rod is worn. Use available reaming fixture and expansion reamer and take light cuts until proper oversize is obtained.

When fitted properly, the pin should fit in the piston with a thumb push with the piston pre-heated to 170°. The pin should fit in the rod bushing with a push fit.

V8-288, 316, 336, 347 Engines

The fit of piston pin should be checked in the piston and also in the rod bushing. When new pistons (with pins), oversize pins, or new rod bushings are installed, honing of bushing or piston pin bosses, or both, may be necessary to effect a proper fit.

The fit of the piston pin in the rod bushing should be .0003" to .0005" loose. Pin and bushing should be dry when checking this fit. If clearance is excessive, as determined by micrometer measurement of inside diameter of bushing and outside diameter of pin, new bushing or oversize pin should be installed.

Fig. 42 Checking bearing clearance with Plastigage

The pin fit in the piston is zero to .0002" loose with pin and piston bosses clean and dry. When clearance is toward the high limit (.0002") pin can be inserted by light hand pressure (pin should not fall through by its own weight).

When clearance is toward the low limit (zero) considerable hand pressure will be required to insert the pin. By using a brass drift, pin can be tapped into place with light pressure. Piston and pin must be at room temperature when checking fit.

V8-324 & 370 Engines

Piston pins are available in standard, .001" and .003" oversizes. If necessary, reaming and honing of the piston pin hole for the installation of oversize pins are satisfactory. The fit of the pin in the piston should be a tight hand push. If considerable hand pressure is required, the pin may be tapped in place with a hammer and brass drift. It is very important that both the pin and piston pin hole be clean and free from oil.

ROD BEARINGS, REPLACE

All Engines

These bearings are of the precision insert type, requiring no reaming or scraping. The bearings are designed for use without shims and under no circumstances should shims be used in order to affect an adjustment.

When installing bearings, be sure that back of the bearing shells as well as the bearings seats in the rods are smooth, clean and dry.

Bearing clearance may be checked with Plastigage and full instructions for its use is furnished in the envelope in which it is contained, Fig. 42.

The bearing inserts are assembled with a slight projection above the rod and cap faces to insure positive contact. Always use new bearings for wear adjustments. If metal is removed from either the cap or face, it will be impossible to use the rod again with a new bearing shell.

MAIN BEARINGS, REPLACE

All Engines

These bearings are of the precision insert type requiring no reaming or scraping. They may be removed and replaced without taking out the crankshaft. Like the rod bearings, main bearings may be checked with Plastigage. Be sure the bearings are smooth and clean on both sides. This applies to the bearing seats as well.

When all the cap bolts are tightened, the crankshaft must turn freely. If it does not, loosen the cap bolts one at a time and try turning the crankshaft to determine which bearing is causing drag. To remedy the condition, replace the tight bearing halves, or, if necessary, lap the crankshaft bearing journal to provide the necessary clearance.

CRANKSHAFT END PLAY, ADJUST

All Engines

Through normal wear end play will seldom become excessive but whenever new bearings are fitted, check the end play by forcing the crankshaft back to the limit of its end play with a pry bar and check the clearance with a feeler gauge between the thrust bearing flange and crankshaft cheek.

If end play is less than .003", the bearing flanges may be dressed down to obtain the desired result. End play in excess of .008" calls for the installation of new thrust bearing shells.

CRANKSHAFT OIL SEAL, REPLACE

228, 248, 270, 302, V8-324, V8-370, V6 and V12

Crankshaft rear bearing oil seal consists of two pieces of special packing. One piece is installed in the groove in the rear bearing cap and the other piece is installed in a similar groove in the cylinder block.

Position the rear bearing seal in the groove in the cylinder block. Lay an improvised mandrel, Fig. 43 in the bearing bore and strike the mandrel with a hammer to drive the seal into the groove.

Fig. 43 Compressing oil seal in rear main bearing cap

Install the seal in the bearing cap in a similar manner. Using a sharp knife, cut off both ends of each seal which project out of the grooves. When cutting off the ends of the seals, do not leave frayed ends which would prevent proper seating of the bearing cap if the ends should extend between cap and cylinder block.

318, 360, 426, 503 Engines

The crankshaft rear oil seal for these engines consists of a leather ring held in close contact with the outer face of the flywheel flange by a spring. The spring-loaded leather seal, with the aid of the oil slinger at the rear bearing, effectively prevents leakage of oil at the rear of the crankshaft.

The seal is pressed into the retainer which is securely bolted to the rear of the crankcase. Whenever the engine is disassembled, the seal should always be renewed regardless of its condition.

The oil seal is readily accessible after the flywheel is removed. Remove the seal and retainer as a unit, then take the seal from the retainer.

Install the new seal, making sure it is square with the hole in the retainer as it is being pressed in place. A special tool consisting of two flat plates and a thrust screw is available to press the seal evenly in the retainer.

Removal, V8-288, 316, 336, 347 Engines

1. Drain oil and remove pan.
2. Remove oil pump and pump drive shaft.
3. Remove oil baffle and cylinder block-to-oil baffle tube (lower oil level indicator tube).
4. Remove transmission.
5. Remove rear center main bearing cap and upper half of its bearing shell. *This will eliminate danger of damaging thrust surfaces of bearing and will also allow crankshaft to be lowered more easily.*
6. Remove rear main bearing cap and loosen remaining bearing caps sufficiently to allow crankshaft to be lowered approximately 3/8" at the rear.
7. With crankshaft lowered to provide clearance, remove upper half of rear main bearing oil seal.

Installation

1. Install seal in cap with one end flush with cap, using a suitable hammer and seal compressor.
2. Remove seal from cap and install in block by slipping it up over crankshaft into seal cavity of block. Insert end which was flush with cap first.
3. Install rear main bearing cap with bearing shell and tighten to 95 lb. ft. torque to pull crankshaft up into place against seal.
4. Take off cap and trim both ends of seal flush with block.
5. Install a new seal in the cap, pack and trim as shown in Fig. 43.
6. Install cap with bearing shell and tighten to 120 lb. ft. torque.
7. Remove bearing cap again and inspect the split line between cap and block to be certain that none of the seal material has been compressed between the two. If it has, scrape it off to insure proper seating of metal surfaces.
8. Reinstall cap and tighten to 120 lb. ft. torque.
9. Reinstall center main bearing and cap and torque to 95 lb. ft.
10. Reinstall other parts removed.

OIL PAN, REPLACE

V6, V12 and In Line 6's

Drain the oil, remove the oil pan attaching screws and lower the pan.

V8-288, 316, 336, 347 Engines

Drain the oil from the pan. Disconnect the exhaust crossover pipe from both manifolds and exhaust pipe. Remove pipe by shifting it around to a position where it will come out without forcing.

Remove the two rear oil pan screws which retain the flywheel housing front shield to the cylinder block. Remove the four screws which retain the shield to the flywheel housing and remove the shield.

Remove flywheel housing lower cover. Loosen crankcase ventilator outlet pipe brace clamp and swing the brace out of the way. Remove the attaching screws and drop the pan.

Reverse the foregoing procedure to install the pan. However, the rear main bearing cap gasket should be removed from its groove in the cap, the groove cleaned thoroughly and a new gasket installed. Apply gasket cement to the groove before installing the gasket.

V8-324 & 370 Engines

To remove the pan take off the starting motor and exhaust crossover pipe (if used). Remove the attaching screws and lower the pan.

Fig. 43A Oil pump on V6-305 and V6-351 engines

OIL PUMP REPAIRS

V6-305, V6-351

After removing the oil pan, remove oil inlet pipe and screen from pump. Remove two bolts attaching oil pump to cylinder block, then remove pump and drive shaft. Disassemble pump as suggested by Fig. 43A, then inspect parts as follows:

1. Inspect ends of drive shaft which engage distributor and oil pump shafts. Replace shaft if excessively worn or damaged.
2. Check fit of inner rotor shaft in body. If excessive wear is indicated at either shaft or body, replace worn parts.
3. Place outer rotor in body and insert inner rotor and shaft in operating position. Check clearance between outer rotor and body and clearance between edge of inner rotor lobe and outer rotor with feeler gauge; if clearance exceeds .006", replace worn parts.
4. With rotors in pump body, place straightedge across rotors and body; then with feeler gauge measure clearance between rotors and straightedge, which should be .0011-.0034".
5. Use straightedge to check rotor side of pump cover for flatness. Also look for grooves and other evidence of wear on cover. Replace cover if not in good condition.

Fig. 43B Oil pump and governor spinner valve. V6-401, 478, V12-702 engines

Fig. 44 Oil pump service details. 228, 248, 270, 302 engines

Fig. 45 Oil pump service details. 318, 360, 426, 503 engines

6. Relief valve spring should have 14.7 to 16.3 lbs pressure when compressed to 1.69". Spring free length should be 2.72".

V6-401, 478, V12-702

After removing the oil pan and oil pump, disassemble the pump as follows, referring to Fig. 43B.

Remove bolts that secure spinner valve cover, rotor cover and spinner housing to pump body and separate parts. Remove outer rotor and shaft and inner rotor from pump body. Remove relief valve spring cap, then remove spring and valve.

Inspection of Parts — Inner rotor and shaft assembly and outer rotor are furnished for service in matched sets. With rotors in pump body, place a straightedge across rotors and body and measure clearance with feeler gauge. Clearance should be .0011-.0064".

Use feeler gauge to check rotor side of rotor cover and spinner housing for flatness. Also look for grooves and other evidence of wear on pump cover.

Clean relief valve parts and check fit of valve in bore of pump. Valve must slide into bore smoothly.

Check fit of spinner valve shaft in cover and spinner valve housing in

Fig. 46 Oil pump. V8-288, 316, 336, 347 engines

cover. If excessive clearance is evident, replace parts as necessary. Inspect thrust washer for wear. Clean passages through spinner shaft and passages including bleed hole in spinner cover.

Soak spinner valve and shaft in solvent, then note fit of valve in shaft. It should be possible to push valve endwise, and spring should move valve to closed position. If valve sticks or appears to be loose in shaft, obtain a new preadjusted valve assembly for use when reassembling pump unit *Since special equipment is required for testing spinner valve operation, the valve adjustment should not be disturbed.*

Assembling Pump and Spinner Valve—

1. Install pressure relief valve parts in pump body in following order: valve, spring and spring cap. Tighten cap securely.
2. Lubricate shaft and inner rotor with engine oil and insert shaft into pump body.
3. Install outer rotor in body, then try turning inner rotor and shaft. Shaft must rotate without drag for six or more revolutions.
4. Install rotor cover and spinner housing and retain with two short self-locking bolts.
5. With oil pump inverted, drop coupling into slot in end of pump shaft. Set spinner valve and shaft in place at coupling, then place thrust washer on shaft and install governor spinner cover.

Six-Cyl. Engines

Conventional gear type oil pumps are used in these engines. After removing the oil pan, the pump is accessible. In servicing the pump, follow the suggestions illustrated in Figs. 44 and 45.

Before removing the oil pump on 308 and larger engines, turn the engine over to bring No. 1 piston up to the firing position, noting the position of the distributor rotor. Do not disturb the distributor position while the pump is off the engine.

Before installing the pump on 308 and larger engines, see that the distributor is still in the No. 1 firing position. After the pump is installed, reset the ignition timing.

V8-288 & 316 Engines

Remove oil pan. While holding pump in place, remove attaching screws. Lower the pump away from the block with one hand while removing the oil pump drive shaft with the other.

Remove oil screen and pressure regulator parts. Detach cover from pump body and take out gears, Fig. 46.

Examine all parts for damage and assemble. Do not attempt to change oil pressure by varying length of pressure regulator spring.

To install, position drive shaft in distributor and oil pump drive gear. Place pump in position in the block, indexing the drive shaft with pump drive gear shaft. Install attaching screws with lock washers and tighten securely.

Removal and installation of pump does not affect distributor timing since the oil pump and distributor drive gear are mounted on the distributor shaft.

Fig. 46A Light duty water pump. V6-305 and V6-351 engines

V8-324 & 370 Engines

The positive gear type oil pump is attached to the rear main bearing cap by three bolts and can be removed without disturbing any of the drive mechanism.

To disassemble the pump, release lock wire and remove screen. Take off the oil screen shroud and remove the snap ring from the extension shaft coupling. Remove the oil pump cover and take out the gears. Remove oil pressure regulator nut, spring and valve.

WATER PUMP, REPLACE

228, 248, 270, 302 Engines

1. Drain cooling system.
2. Remove fan belt.
3. If engine is equipped with air compressor, loosen idler pulley mounting bolt to permit belt removal. Remove belt and idler pulley bracket.
4. Remove heater, by-pass fittings, or air compressor water lines (if used) from thermostat housing and water pump.
5. Remove hose from water outlet and from water pump inlet.
6. Remove thermostat housing.
7. Unfasten and remove water pump and fan. *The bolt with the screwdriver slot cannot be removed from pump until pulley has been removed.* In some cases the pump may be removed easier if the fan blades are taken off the pump before removing the pump from the engine.
8. Reverse the foregoing to install the pump.

318, 360, 426, 503 Engines

1. Drain cooling system.
2. Remove fan blades and spacer (if used). If truck is equipped with a fan shroud, place blades in shroud.
3. If air compressor is used, loosen swivel bolt nut at bottom of air compressor, then remove cap screw in slotted support which attaches support to pump.
4. Move compressor toward engine and remove drive belt.
5. Loosen cap screw in slotted arm at generator. Loosen pivot bolts at bottom of generator support bracket, then remove cap screw which attaches adjusting arm to water pump.
6. Swing generator toward engine and remove drive belts.
7. Loosen clamps on by-pass hose.
8. Disconnect inlet tube at water pump and discard gasket. Disconnect heater hose (if used).
9. Unfasten and remove water pump from engine block.
10. Reverse the foregoing procedure to install the pump.

V8-288, 316, 336, 347 Engines

To remove the pump, drain the cooling system. Remove fan belt, fan and pulley. Unfasten the pump from the block and lift it off.

Install the pump in the reverse order. When pump is installed, drain hole will be at the bottom.

V8-324 & 370 Engines

To remove the pump take off the fan and pulley. Unfasten the pump from the block and lift it off.

When installing the pump, one side of the pump bearing housing gasket should be coated with gasket cement. The four bearing housing bolt threads should be dipped in a suitable sealer.

WATER PUMP REPAIRS

V6 and V12 Engines

Light Duty Water Pump, Fig. 46A— When disassembled, clean and inspect pump body and impeller. Shaft and bearing assembly and seal must be replaced whenever pump is disassembled. Surface contacted by seal on impeller hub must be smooth and flat. To assemble pump, first be sure bore through pump body is clean and free from burrs.

1. Install shaft and bearing assembly in pump body, pressing on bearing outer race. Proper location of bearing and shaft is indicated in Fig. 46A. Measure from rear face of body to bearing as shown ($\frac{11}{16}$").
2. Coat outer surface of seal which fits into pump body with sealing compound, then press seal into body.
3. Press flange on front end of pump shaft to the dimension shown (2⅞").
4. Install impeller on rear end of pump shaft, using pressure on rear face of impeller hub while supporting front end of shaft. Locate impeller so a space of ⅜" exists between impeller and pump body.

Heavy Duty Water Pump, Fig. 46B— When disassembled, clean and inspect pulley and impeller. Use new seal and shaft and bearing assembly when reassembling pump. If surface contacted by

Fig. 46B Heavy duty pump. V6-401, 478, V12-702 engines

seal at impeller hub is not smooth and flat, install new impeller. To assemble pump, proceed as follows:

1. Support pump body at mounting flange and press on bearing outer race to install bearing and shaft assembly. *Press bearing into body only far enough to permit installation of snap ring.* Front edge of bearing to be $3\frac{11}{16}$" from rear face of body flange.
2. Install snap ring in groove in body. Coat outer surface of seal which fits into pump body with sealing compound, then press seal firmly into body.
3. Support front end of pump shaft and press impeller onto rear end of shaft to .900" dimension shown in Fig. 46B. Measure from outer edge of impeller blade to surface of body flange.
4. Install key in slot in shaft. Install pulley and retain with self-locking nut.

228, 248, 270, 302 Engines

The pump used on these engines, Fig. 47, is of the sealed ball bearing type packed with lubricant at the time of manufacture. When disassembling, carefully note the arrangement of the seal parts so that correct assembly may be assured.

Never soak the shaft and bearing assembly in cleaning solvent because it will dissolve the lubricant. To clean the shaft and bearing, merely moisten a cloth in cleaning fluid and wipe away any surplus lubricant or other foreign matter.

Be sure the face of the housing against which the seal washer turns is smooth and free of scores.

318, 360, 426, 503 Engines

The pumps used on these engines are of the removable ball bearing type, Fig. 48. When disassembling, note the arrangement of the seal parts so that the new parts will be assembled correctly.

V8-288, 316, 336, 347 Engines

The water pump, Fig. 49, is of the sealed ball bearing type. A repair kit containing a seal assembly and shaft and bearing assembly is available for repairing the pump.

When assembling the pump, be guided by the dimensions shown in the illustration and proceed as follows:

1. Be sure the bore through the pump body is smooth and clean.
2. Install the shaft and bearing in the pump body, pressing on the bearing outer race.
3. Coat the outer surface of the seal which fits into the pump body with sealing compound, then press the seal assembly into the pump body.
4. Press the flange on the front end of the pump shaft to the dimension shown in Fig. 49.
5. Install the impeller, using pressure on the rear face of the impeller hub while supporting the front end of the shaft. Locate the impeller as shown in the illustration.

V8-324 & 370 Engines

The water pump double row bearing has one large groove in the center and two smaller grooves toward one end. The end with the two smaller grooves must always be assembled into the pump housing first. This end of the bearing shaft will then be at the impeller end of the pump.

To assemble the pump, press the seal into the housing. Press the bearing into the housing until the bearing seats on shoulder in housing. Install the bearing retainer spring at the front end of the housing. Support the impeller and press the bearing shaft through the impeller until the bottom edge of the vanes are 13/16" from the machined face at edge of housing.

RADIATOR, REPLACE

Conventional Models 1000 Thru 5000

1. Unfasten fan shroud (if used) from radiator. Position shroud back over fan blade.
2. Disconnect hoses at radiator. If necessary, remove hoses and hose connection pipes.
3. Unfasten radiator from its support and lift out radiator.

Models P1500 and P2500

1. Jack up and block front of vehicle approximately 10" from floor. Radiator with its support is removed as a unit as follows:
2. Remove grille and stone shield.
3. Remove capscrew which attaches frame bracket to radiator support at each side.
4. Inside vehicle under dash, remove closure paneling and disconnect radiator filler tube.

Fig. 47 Sealed ball bearing type water pump. 228, 248, 270, 302 engines

Fig. 48 Typical removable ball bearing type water pump. 318, 360, 426, 503 engines

Fig. 49 Water pump. V8-288, 316, 336, 347 engines

Fig. 50 Ignition details. V8-288, 316, 336, 347 engines

Fig. 51 Ignition details. V8-324, 370 engines

Fig. 52 Ignition details. V6 and V12 engines

5. Remove two nuts and springs from radiator support hold-down U-bolt. Push U-bolt up through frame crossmember.
6. With aid of an assistant, carefully lower radiator with support forward of front crossmember.
7. When installing, tighten support U-bolt nuts until springs are compressed to a length of $1\frac{1}{16}''$.

"B" Models 4000 and 5000

1. Remove hood center and side panels as a unit.
2. Remove radiator support top diagonal rod. *Do not move inner nut at radiator end of rod which will assure proper alignment when reinstalled.*
3. Disconnect and remove radiator hoses and connecting tube.
4. Unfasten fan shroud from radiator. Position shroud rearward and to right to clear air compressor (if equipped).
5. With an assistant or a hoist to retain radiator safely, unfasten radiator from support and lift out radiator.

"L" Models

1. Tilt cab forward, then remove or position engine controls over radiator to one side to permit removal of radiator.
2. Disconnect upper and lower hoses at radiator.
3. Detach radiator side flange from radiator support.
4. Move radiator forward and carefully raise it from vehicle.

Models 100 to 500

1. Remove water hoses.
2. On diesel models, disconnect air supply lines at radiator shutter thermostat.
3. Unhook wiring harness from clips on radiator support crossbar.
4. Remove radiator upper baffle extension.
5. Remove radiator support crossbar.
6. Unfasten radiator support from its mounting and lift it out. On diesel models, remove fan shroud.
7. Reverse procedure to install.

Models 520 to 980, Conventional

1. Remove hood and grille.
2. Disconnect wiring at right-hand junction block.
3. Unclip loom from radiator shell.
4. If equipped with air-operated shutters, disconnect air feed line at shutter thermostat. If equipped with manual shutters, disconnect cable and conduit from trunnion and clamp at radiator.
5. Remove radiator tie rod and radiator-to-dash brace rods.
6. Unfasten radiator from its support.
7. Remove water hoses.
8. Remove radiator with shell and shutters as a unit from the chassis. Note number of shims (if any) used at support U-bolt.
9. Install in reverse order, being sure to replace shims found at support U-bolt.

Fig. 53 V12 ignition distributor with cover removed

Models 520 to 980, C.O.E.

1. Radiator is most easily removed separately from its support, leaving shutters (if used) attached to support.
2. Remove radiator top baffle.
3. If equipped with self-powered thermostat type shutter, detach shutter control rod from shutter.
4. If equipped with air-operated shutters, disconnect both air lines from thermostat and unscrew thermostat from radiator. Disconnect air line from air cylinder and remove air line from opening through radiator top tank.
5. If equipped with manual-operated shutter, detach shutter control rod from shutter. Disconnect cable and conduit from trunnion and clamp at radiator.
6. On all models, remove water hoses and radiator outlet elbow.
7. Remove radiator support crossbar.
8. Remove fan shroud (if used).
9. Lift radiator from vehicle.
10. Reverse procedure to install.

IGNITION TIMING

All Except V-12's

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder it at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

V-12 Engines

Timing Left Bank—Connect timing light to No. 1 spark plug wire, Fig. 52. Start engine and run at idling speed while directing light beam toward pointer in front end cover. If correctly timed, the 5° line for No. 1 cylinder on pulley will be aligned with pointer as flash occurs. If not, loosen clamp screw at base of distributor and turn distributor as necessary to synchronize flashes with 5° timing mark.

Important: The foregoing must be done first when timing engine and must be followed by timing the right bank. Any change in left bank timing will result in a corresponding change in right bank timing.

Timing Right Bank — Connect timing light to No. 2 spark plug wire, Fig. 52, after timing has been set on left bank. Remove cover from top of distributor to expose distributor points and adjusting screws, Fig. 53.

Start engine and run at idle speed while directing light beam toward timing pointer on engine front cover. If timed correctly, the 5° line for No. 2 cylinder on pulley will be aligned with pointer as flash occurs.

If right bank is not timed properly, loosen two plate lock screws (4, Fig. 53) and turn right bank adjusting screw (2) as necessary to synchronize flash with 5° mark for No. 2 cylinder on pulley. Tighten plate lock screws and install distributor cover.

Fig. A Carburetor and linkage adjustments on V12 engines

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if the fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading on carburetors with automatic choke may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Fig. B Aligning carburetor throttle linkage on V12 engines

Dirty or Rusty Automatic Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

V-12 Carburetor and Linkage Adjustments

1. Seat idle mixture screws lightly on each carburetor, then back off 1¼ turns as an initial setting.
2. Referring to Figs. A and B, adjust the choke linkage so that it opens and closes both choke valves simultaneously. If both choke valves will not close completely when knob is pulled outward, end of control wire conduit may not be located properly in carburetor clamp to allow full travel of choke lever upon closing.
3. Disconnect accelerator control rod (4) at accelerator idler lever (5). This will allow free movement of carburetor linkage without moving accelerator linkage.
4. Loosen clamp screw (12) which secures hand throttle control wire to front carburetor hand throttle lever (11).
5. Back out idle stop screw (15) at each carburetor to allow throttle plates to close completely.
6. Pull socket at forward end of throttle interconnecting link (6) from lower end of front carburetor throttle shaft lever (9). While holding lower end of throttle shaft lever of front carburetor rearward (throttle plates closed), force throttle link (6) rearward to place rear carburetor throttle plates in closed position. Referring to Fig. B, shorten or lengthen throttle link (6) by turning hex turnbuckle at forward end of link to align throttle lever ball stud with center of turnbuckle swivel socket. Check linkage action.
7. While holding throttle plates closed, turn idle stop screw of front carburetor inward two complete turns from the completely closed position. This is an initial setting which will permit engine to start and operate until final idle speed adjustment is made later (adjustment of stop screw at rear carburetor should be made later).
8. Connect accelerator control rod (4) to accelerator idler lever (5).
9. Press hand throttle control knob inward on control panel. At front carburetor, raise hand throttle lever (11) to just contact throttle shaft lever (9). With lever held in this position, tighten screw (12) clamping hand throttle wire to swivel of hand throttle lever (11). Check hand throttle action.
10. Make sure transmission is in neutral, start engine and run at a fast idle until engine operating temperature is reached.
11. Turn front carburetor idle stop screw (15) to slow idle (400-450 rpm).
12. Connect vacuum gauge to the ⅛" tapped hole at upper left rear side of either carburetor. Remove plug from hole to install gauge.
13. Set both idle mixture screws (14) of either carburetor together to give the highest steady manifold vacuum reading. If vacuum gauge is not available, adjust to provide the smoothest running and maximum idle speed. This can be done by turning both mixture screws in until engine begins to slow down, then back the screws off over the "high spot" until it again begins to slow down. A position midway between the two "slow downs", slightly on the rich side, will give satisfactory idle mixture setting. Repeat this procedure on the other carburetor. Final adjustment may vary slightly from these settings but should not exceed ¼ turn difference between the screws.
14. If the foregoing adjustment results in increased idle rpm, reset front carburetor idle stop screw (15) to obtain desired idle rpm, then make a final idle mixture adjustment on both carburetors.
15. When desired idle stop and mixture adjustments are obtained, adjust the rear carburetor idle stop screw to just contact stop in idle position. Screws of both carburetors should contact stop simultaneously.
16. Check accelerator linkage for free action and travel. Adjustment of accelerator linkage is accomplished by adjusting the length and travel of accelerator rods and idler lever. Carburetor throttle plates should be in full-fuel position when pedal is held ⅛" from floorboard, otherwise damage to linkage may occur, or full throttle opening may not be obtained. Adjustment of linkage can be made at point (10). Shorten or lengthen rods as necessary.

HOLLEY NOTES

Fig. ①—Measured from flange surface of air horn to bottom of float (not soldered seam).

②—Three holes in pump link. Middle hole for average conditions, outer hole (long stroke) for cold weather, and inner hole (short stroke) for hot weather.

③—Measured from top surface of bowl to surface of fuel.

④—See carburetor text for data on this electric choke.

Fig. ⑤—Level of fuel to outer surface of main body, measured through economizer hole.

ZENITH NOTES

Series 228, 63 Carbs.

For vehicles operating 3000 feet or higher above sea level, an adjustable jet may be used in place of the main jet lower plug. To adjust, accelerate engine speed comparable to 30-35 mph road speed, turn adjustment in until engine runs unsteadily, indicating too lean a mixture, then turn adjustment out until engine runs smoothly.

④—Apply light closing pressure to choke valve, then open throttle valve fully. Choke valve should open just enough to insert a rod of the thickness listed between choke valve and wall of air horn. Adjust by bending ear of cam lever.

STROMBERG NOTES

Fig. ①—WW float level.

②—From closed to wide open position. Bend pump rod to adjust.

③—With throttle valves fully closed, turn throttle stop screw in just to the point of contact with throttle shaft lever. Then turn stop screw in the number of turns listed to open throttle valves. With choke valve closed, insert a $\frac{1}{16}$" drill rod between ear on contact lever and first step of fast idle cam. Adjust by bending cam contact ear.

Fig. ⑤—With choke valve held open and throttle valves full closed, distance between top of pump link and top of air horn should be as specified. Setting is gauged with pump rod in outer hole of throttle lever.

CARBURETOR GOVERNOR

King-Seeley Type

This governor, Fig. 1, is mounted between the carburetor and intake manifold and automatically governs the maximum speed at which the engine may be operated.

The gas mixture rushing from the carburetor through the governor throat strikes the offset throttle valve and tends to draw it closed. This action is opposed by a governor spring which is attached to the valve shaft through a cam ribbon and cam. By adjusting the pull of this spring, the governor valve may be made to remain open, and then closed at a predetermined engine speed. Adjustment of the spring pull is accomplished by changing the number of coils operating.

Governor Adjustment

All governors are calibrated and adjusted in assembly to insure accurate control of the maximum engine speed of the model vehicle for which it is intended. However, there will be occasions when minor adjustments are required to satisfy local conditions where the truck is operating.

To adjust a governor for higher speed, turn the adjusting cap counter-clockwise or to the left; for lower speeds turn the cap to the right or clockwise. One turn on the adjusting screw will change the speed 300-400 rpm or between 4 and 5 mph.

When a more sensitive regulation is desired or if the governor is too sensitive and inclined to surge, correct the adjustment as follows by means of the calibrating nut shown at "A," Fig. 2.

If Governor is too Sensitive—If the governor is too sensitive or on the point of surging, remove the adjusting cap and hexagonal shaft assembly and place the special hollow wrench (A-24283) in position on nut "A". Insert the special adjusting wrench (A-25264) through this wrench and turn the main adjusting screw "B" to the right one turn. (These wrenches are available at King-Seeley Distributors.) With the hollow wrench in the slot of nut "A" turn this nut to the right about ¼ turn. The main adjusting screw "B" must be kept from turning while nut "A" is adjusted.

Fig. 2 King-Seeley governor adjustments

Fig. 3 Holley 1174 governor

Holley Model 1174

Used with Holley carburetors, this governor, Fig. 3, is a vacuum controlled device featuring all the advantages of a mechanical governor without lengthy and complicated linkage. Should it become necessary to make any changes, proceed as follows:

To adjust the governor cut-off speed, remove the seal from the screw on the side of the governor housing and remove the screw. Rotate the engine until the end of the governor rotor, which carries the adjusting screw, is in line with the hole from which the screw was removed. Turn the adjusting screw clockwise to increase or counter-clockwise to decrease governed speed.

Whenever the governor has been disassembled and serviced, after reassembling turn the adjusting screw clockwise until it stops, then turn it counter-clockwise three full turns. Final adjustment is made after the governor has been assembled to the engine.

The vacuum adjusting screw regulates the rpm spread between the governor full load cut-off speed and the no-load engine speed. Turning the screw clockwise will decrease the rpm spread. Turning it counter-clockwise will increase the spread. Changing the position of the screw will change the average governor speed and this should be corrected by the rotor adjusting screw.

Fig. 1 King-Seeley governor

AUTOMATIC CHOKE

Electric Type

Used on some Holley and Zenith carburetors with Hydra-Matic, this type choke, Fig. 4, controls the opening and closing of the air shutter (choke) during the entire range of engine operation. It is directly connected to the air shutter shaft which assures positive action and accurate control under various operating temperatures.

Manifold vacuum is used to partially open the air shutter after the initial firing of the engine, and heat is used on the

Fig. 4 Electric type automatic choke used on 1955-56 Holley and Zenith carburetors (down-draft type shown)

thermostat spring to control the amount of opening during warming up period. Heat for the thermostat is provided by an electric element in the thermostat chamber.

The electrical connection from the automatic choke should be to the ignition switch so that current will flow only when the ignition switch is turned on.

Thermostat Adjustment

It may be necessary in some cases to increase or decrease the tension of the thermostat so as to provide smooth engine performance during the warm-up period. This can be done by loosening the three screws of the cover plate so that the cover may be turned to the position best suited for the particular installation. The arrow indicates the direction to increase the tension and enrich the mixture. To examine and check the thermostat, proceed as follows:

1. Remove cover plate and allow the thermostat to cool or warm until it has reached a temperature of 70°. *This is very important and should be done in a room having a temperature of 70°.*
2. When the temperature reaches 70°, the inside of the eyelet at the end of the thermostat coil spring should coincide with the "O" mark on the outside of the cover, Fig. 5, which is the original setting made at the factory.
3. If the "O" mark does not coincide with the eyelet at this temperature, compensate the differential (number of notches) when setting the thermostat later.
4. To adjust the thermostat, place cover on case so the eyelet is in position over lever pin with no tension on the thermostat and with the air shutter in wide open position. The "O" mark on cover will be 3 to 4 graduations to the right of the indicator line on the case. Move the cover to bring the "O" mark up to the indicator line.
5. Turn cover 15 notches in direction of the arrow.

Fig. 5 Eyelet aligned with "O" mark on cover

Service Note

If it is impossible to maintain a room temperature of 70°, provide for the difference by allowing one graduation on thermostat cover for each 5-degrees variation in temperature. For example, if the temperature is 60°, the eyelet on the thermostat spring will coincide with the second graduation to the left of the "O" mark. If the temperature is 80°, the eyelet will coincide with the second graduation to the right of the "O" mark.

Clutch Section

CLUTCH PEDAL, ADJUST

Linkage Type

If clutch pedal free travel is less than ¾", turn forward adjusting nut toward front of adjusting rod until free travel of 1" is obtained. Tighten rear nut to lock adjustment. Turn nuts in opposite direction to decrease free pedal travel after installing new clutch parts.

Additional adjustment can be obtained if necessary by changing the length of the clutch pull rod. The adjustable yoke at the front end of the pull rod can be repositioned as required. Tighten yoke nut firmly after making adjustment.

HYDRAULIC CLUTCH CONTROLS

1960-63

This system, Fig. 1, utilizes hydraulic pressure as a means of transmitting clutch pedal movement to the clutch release mechanism. The system consists of a pedal-operated master cylinder and a slave cylinder, interconnected with hydraulic lines. The clutch pedal is connected to the master cylinder push rod and the slave cylinder push rod is connected to the clutch throwout lever.

Fig. 1 Hydraulic clutch control system

Maintenance

To maintain proper clutch operation, the system should be checked and serv-

Fig. 2 Slave cylinder push rod adjustment

iced periodically as follows:

1. Maintain proper level of hydraulic fluid in master cylinder. At least once a year drain and flush entire clutch system and refill with new fluid.
2. Inspect entire clutch system regularly for fluid leakage. Leakage must be corrected immediately.
3. Make sure return spring at slave cylinder is not weak or broken.
4. Check and adjust if necessary the clutch pedal linkage as outlined below.

Clutch Control Linkage, Adjust

Two adjustments are required to obtain proper clutch control operation: Master cylinder push rod and slave cylinder push rod.

The purpose of the master cylinder push rod is to make sure the piston is resting all the way back against the piston stop with the end of the push rod barely contacting the piston. If the push rod is adjusted too long, the piston may never return far enough to clear the compensating port in the cylinder. This seals the line and the result is the same as riding the clutch all the time. If the push rod is too short, the pedal must be depressed too far before clutch disengages.

The slave cylinder push rod adjustment obtains the specified distance between the tip of the wedge at end of push rod and bottom of V-slot at end of clutch release fork when cylinder is not pressurized and release fork and bearing are held just in contact with clutch release levers. Clearance between these two points should measure ¼″ to $\frac{5}{16}$″, Fig. 2.

A slight reduction in pedal free travel at high engine rpm is normal; it is the result of centrifugal action on the clutch release lever weights. Do not change adjustment to obtain a definite free pedal travel dimension.

Before making adjustments, the hydraulic system must be free of air and the master cylinder must be filled to ½″ below filler opening.

Master Cylinder Push Rod, Adjust

Before making adjustment, pull master cylinder boot back on push rod. Visually check to see that piston is firmly seated against piston stop. If it isn't, push rod is too long and should be shortened.

Conventional and "B" Models — Loosen lock nut on master cylinder push rod and turn hex portion of push rod as necessary to provide 0 to ⅛″ free travel before push rod contacts master cylinder piston. Tighten lock nut on push rod.

On early production 1960 vehicles, an eccentric bolt was used to attach push rod to pedal. On these vehicles, the adjustment must be made by turning the eccentric bolt.

Model SP5000 — From underneath the vehicle, loosen nut on eccentric bolt, Fig. 3, which attaches pedal to master cylinder push rod. Turn eccentric bolt to obtain ⅛″ (measured at pedal pad) before push rod contacts master cylinder piston. Hold eccentric bolt in this position while tightening lock nut.

Slave Cylinder Push Rod, Adjust

1. Disconnect clutch release fork retracting spring at side of clutch. *Do not apply pressure on clutch pedal while spring is disconnected.*
2. Bottom slave cylinder push rod and piston by pushing slave cylinder push rod toward front of engine as far as it will go.
3. Pull clutch release fork toward rear end of engine until clutch release bearing just contacts pressure plate release levers.
4. Referring to Fig. 3, measure clearance between bottom of V-slot in release fork and pointed tip of wedge on slave cylinder push rod. Clearance should measure ¼″ to $\frac{5}{16}$″. If necessary, adjust by turning adjusting nut at rear of wedge. Adjusting nut is the self-locking type. After making adjustment, connect clutch release fork return spring.

Fig. 3 Hydraulic clutch control linkage. Model SP5000

Bleeding System

The need for bleeding air from the system is generally indicated by a springy, spongy pedal action. The presence of air in the system is the result of low fluid level in the main cylinder, or if some part of the system has been opened. A bleeder valve is provided at the slave cylinder alongside of clutch.

The clutch master cylinder is accessible under the hood on conventional and "B" models, inside the cab and under dash on "L" models, and through the access door on "SP" models.

The plain end of bleeder hose can be slipped over end of bleeder valve. And the system can be bled by either the pressure or manual method in the same manner as when bleeding hydraulic brakes.

DIAPHRAGM SPRING CLUTCH

Removal

1. Remove transmission.
2. Remove clutch throwout bearing from fork.
3. Remove lock nut from adjusting link and remove clutch fork by pressing it away from ball mounting with a screwdriver until fork snaps loose from ball.
4. Install a suitable pilot tool to support clutch during removal.
5. Loosen clutch attaching bolts one turn at a time to prevent distortion of clutch cover until diaphragm spring is released.
6. Remove clutch pilot tool and take clutch from vehicle.

Disassemble

1. Remove three drive strap-to-pressure plate bolts and retracting springs and remove pressure plate from clutch cover. *When disassembling, note position of "O" marks on pressure plate and cover. These marks must be aligned when assembled to maintain balance.*
2. The clutch diaphragm spring and two pivot rings are riveted to the clutch cover. Spring, ring and cover should be inspected for excessive wear or damage and if there is a de-

fect, it is necessary to replace the complete cover assembly.

Inspection

1. Wash all parts except throwout bearing in cleaning solvent. *The throwout bearing is permanently packed with lubricant and should not be soaked in cleaning solvent as this may dissolve the lubricant.*
2. Inspect pressure plate and flywheel for scores on the contact surfaces.
3. Check drive straps for looseness at the clutch cover rivets and for evidence of looseness at the pressure plate bolt holes.
4. Check throwout bearing for roughness and for free fit on sleeve of transmission clutch gear bearing retainer.
5. Check run-out of transmission pilot hole in clutch housing by removing a flywheel bolt and installing a dial indicator. Run-out should not be more than .008".
6. Check fit of ball in clutch fork. This fit should be snug without end play.
7. Inspect clutch disc for worn, loose or oil soaked facings, broken springs, loose or riding rivets.

Fig. 5 Adjusting points on Lipe-Rollway ML clutch

Fig. 4 Lipe-Rollway Type ML clutch

8. Examine splines in hub and make sure they slide freely on splines of transmission clutch shaft. If splines are worn, the clutch should be replaced.

Assemble

1. Install pressure plate in cover, lining up "O" mark [on pressure plate with "O" mark] on flange of cover.
2. Install pressure plate retracting springs and drive strap-to-pressure plate bolts and lockwashers and torque to 11 lb. ft. The clutch is now ready to be installed.

Installation

1. Hand crank engine until "X" mark on flywheel is at the bottom.
2. Install clutch assembly, supporting it with a suitable pilot tool.
3. Turn clutch assembly until "X" mark on clutch cover flange lines up with "X" mark on flywheel.
4. Install attaching bolts and tighten each one a turn at a time to prevent distorting the cover as the spring pressure is taken up.
5. Remove the clutch piloting tool.
6. Pack clutch fork ball seat with a small amount of high melting point grease and install a new retainer in the groove of the clutch fork if the old retainer is worn or damaged. *Install retainer with high side up, away from bottom of ball socket and with open end of retainer on the horizontal.*
7. Replace clutch fork on fork ball in clutch housing by snapping it onto the ball.
8. Lubricate recess on inside of throwout bearing collar and coat throwout fork groove with a small amount of graphite grease.
9. Install throwout bearing to the throwout fork.
10. Install the transmission.

LIPE-ROLLWAY TYPE ML

This clutch, Fig. 4, is a single plate, dry disc type in which pressure on the driven disc is provided by a heavy spiral spring acting through 20 interlocked levers.

Clutch Adjustment

The original setting of the clutch provides for 1½" free movement of the clutch pedal. As the facings wear the clutch sleeve moves toward the clutch release bearing, reducing the clearance and automatically cutting down on the free travel of the clutch pedal. When this travel drops to ½", the clutch should be readjusted.

Never wait for the clutch to start slipping before adjusting it. It may then be too late to make an adjustment. Clutch facings quickly disintergrate once they become burned through slippage, and both facings and pressure plate are short lived thereafter.

Fig. 6 Removing shims to establish Dimension "A". Lipe-Rollway ML clutch

Do not adjust the clutch pedal linkage until the clutch has been adjusted to the correct Dimension "A", Fig. 5. The correct dimension "A" for the clutches used are as follows: *Clutches may be identified by the manufacturer's number stamped on a name plate or on the cover or flywheel ring.*

Clutch No.	Dimension "A"	Shims Req.①
120- 1-314	$1\frac{1}{16}''$	6
130- 1-117	$1\frac{1}{16}''$	8
130-41-487	$1\frac{1}{16}''$	8
140- 1-116	$1\frac{3}{16}''$	8
140-41-483	$1\frac{3}{16}''$	8
150- 1-316	$1\frac{3}{16}''$	7
150-41-486	$1\frac{3}{16}''$	8

① Removal of one shim, .015″ thick is equivalent to reducing Dimension "A" by $\frac{3}{32}''$. The number of shims listed for each clutch should be placed under each strap when overhauling the clutch.

1. To adjust the clutch, block the clutch pedal in the depressed position. This is important, otherwise the straps and studs may become bent.
2. Back off adjusting nuts five full turns.
3. Remove pedal block. This will allow the adjusting plate to move out of contact with the adjusting shims.
4. Remove a sufficient number of shims to obtain Dimension "A". It is usually sufficient to remove only one shim from each stud, Fig. 6, then checking Dimension "A" before removing more. *Be sure no portion of the shim is torn and remains under the flange of the adjusting plate and that an equal number of shims remain under each strap.*
5. Reblock the clutch pedal. This moves the adjusting plate into contact with the adjusting shims. Then tighten each adjusting strap nut firmly.
6. Recheck Dimension "A".
7. After correct Dimension "A" has been established, adjust the vehicle clutch release linkage so as to obtain proper clutch release bearing clearance of $\frac{1}{8}''$ to $\frac{3}{32}''$ as indicated in Fig. 7.

Clutch Driven Disc, Replace

1. After removing the transmission, remove the cap screws holding the clutch to the flywheel and remove the clutch and driven disc.
2. Remove the flywheel ring stud nuts and adjusting straps one at a time and place the correct number of shims (see table above) under each strap.
3. Examine flywheel, making sure friction face is clean, smooth and dry.
4. Check release bearing and pilot bearing to make sure they are in good condition. Both these bearings are factory sealed and require no further lubrication.
5. Install a new driven disc and bolt the clutch to the flywheel, using a spare splined shaft to align the disc. When bolting the flywheel, screw in each bolt until it just contacts the cover plate, then gradually tighten alternate bolts until the clutch is drawn up evenly against the flywheel. Tighten remaining clutch-to-flywheel bolts.
6. After clutch is installed, check for proper release. Adjust clutch and pedal linkage as outlined above.

Pressure Plate, Replace

A pressure plate dished in excess of .015″ or badly scored should be replaced with a new part. After removing the transmission and the clutch from the flywheel, proceed as follows:

1. Place clutch on arbor press with pressure plate down and compress spring as far as possible.
2. Remove four retractor springs after first removing pins.
3. Slowly release arbor press, allowing clutch spring to return to normal position.

Fig. 8 Lipe-Rollway 14" dual disc clutch

4. Holding clutch assembly together by hand, turn it over and carefully lift off pressure plate.
5. Install new pressure plate, turn clutch assembly over and compress in arbor press.
6. See that retractor springs are in place and install pins.
7. Remove clutch from press and reinstall on flywheel.

LIPE-ROLLWAY DUAL DISC CLUTCH

Clutch Pedal Adjust

If free movement of the clutch pedal is less than 1½", change the length of the linkage between the idler shaft inner lever and throwout shaft lever. Make sure lock nuts are securely tightened against adjusting nut or yoke after completing adjustment.

Clutch Removal

After removing the transmission, install three ⅜-16 x 2½" hold-down bolts with flat washers through holes in clutch cover. Pressure plate bosses are tapped to receive hold-down bolts.

Since it is possible to assemble the clutch on the flywheel in more than one position, match marks should be placed on cover and flywheel before separating these parts. Remove capscrews attaching clutch cover to flywheel and take off cover and pressure plate assembly and rear driven disc.

Mark intermediate shaft and flywheel so plate can be reinstalled in original position. Remove intermediate plate and forward driven disc from flywheel.

Clutch Disassemble, Fig. 8

Whenever visual inspection of pressure plate, release levers and related parts indicates excessive wear, need for machining or replacement of worn parts, it is necessary to disassemble the clutch cover. A straight-edge and feeler gauge can be used to check for warpage of pressure plate and intermediate plate.

1. Place assembly on arbor press, using blocks as necessary to support clutch at pressure plate surface. Compress assembly to relieve spring pressure. Then remove lock nuts and hold-down bolts.
2. Release press slowly to gradually relieve pressure on springs. Lift cover off springs and remove springs and insulating washers from pressure plate bosses.
3. Remove cotter pins from lever-to-pressure plate pins, withdraw pins and separate lever and eye-bolt assembly from pressure plate.

Fig. 9 Long 11" dual disc clutch

Fig. 7 Clearance between release sleeve and release bearing should be ⅛" to 3/32". Lipe-Rollway ML clutch

Clutch Assemble, Fig. 8

A light application of high melting point grease such as Lubriplate 320 should be applied at driving lugs on pressure plate and at release lever pins as parts are assembled.

1. Make up three assemblies of release lever, links, pins and eye-bolts. Screw adjusting nut into eye-bolt so that three or four inner threads are visible at nut.
2. Locate release lever assemblies and retracting springs at pressure plate, then drive pressure plate pin in with cotter pin hole parallel to pressure plate. Install cotter pin.
3. Lay pressure plate and release lever assembly on blocks or spacers on arbor press bed. Place any necessary shims or spacing washers (required if intermediate plate or pressure plate was ground) on spring bosses, then install insulating washers and springs. Use 15 springs for use with 6-71 engine; with 4-71 or 503 engine, use 12 springs, omitting the center spring in each group.
4. Locate "0" marks on outer edge of cover and pressure plate. With "0" marks adjacent, lower cover into place over pressure plate and springs, making sure springs enter seats in cover. Lay a bar across cover and turn press ram down against bar.

5. Insert guide bolts (1½-20 x 3") through holes in cover and thread bolts into adjusting nuts. Use bolts to guide adjusting nuts through holes in cover as cover is forced down with press. Remove guide bolts and install lock nut on each adjusting nut. *Final adjustment of release levers is made after clutch is assembled to flywheel.*
6. Install three hold-down bolts (⅜-16 x 2½") with flat washers through clutch cover and thread into tapped spring bosses in pressure plate.
7. Remove assembly from press and install on flywheel.

Clutch Install

1. Lubricate and install pilot bearing. Apply a small amount of Lubriplate 320 in pilot bearing cavity in crankshaft; also coat transmission drive gear splines and driving lugs on intermediate plate with same lubricant.
2. Place forward driven disc at flywheel with stamped "Flywheel Side" next to flywheel. Referring to match marks made during removal, position intermediate plate at flywheel with drive lugs engaging drive pins in flywheel.
3. Place rear driven disc against intermediate plate with deflector to rear, away from intermediate plate. Insert a suitable aligning arbor through driven discs and into pilot bearing to support discs while installing cover assembly.
4. Set clutch cover assembly against flywheel with match marks indexed. Install cover to flywheel bolts. Try withdrawing aligning arbor from time to time as cover bolts are tightened to assure that arbor fits freely in splines.
5. Remove three hold-down bolts. Then, using a straightedge across cover and a measuring scale, turn adjusting nut to position the lever thrust button one inch from straightedge. Make adjustment at each lever and tighten lock nuts. Recheck to see that all release levers are identically adjusted.
6. Assemble release mechanism at clutch housing. Spring must hold release bearing support in contact with yoke and parts must operate freely. Grease cup at outer side of housing must be turned down to provide lubrication at release bearing and at surface of drive gear bearing retainer.
7. Install transmission and adjust clutch pedal for free play.

LONG DUAL DISC CLUTCH

Clutch Pedal Adjust

If free movement of the clutch pedal is less than 1½" turn the adjusting nut on fork adjusting rod as necessary to provide 1½" free pedal travel. Make sure jam nuts hold spring against release fork with sufficient tension to seat fork firmly against adjusting nut.

Clutch Removal

1. After removing transmission, mark edge of clutch cover plate and adjacent boss on flywheel.
2. Turn flywheel so two clutch cover bolts are at top. Loosen bolts a few turns but do not remove until other four bolts have been loosened. Turn flywheel as necessary to allow use of socket wrench to loosen remaining bolts.
3. When spring pressure is completely relieved, remove bolts and lift off clutch cover, rear driven disc, center drive plate and front driven disc.

Clutch Disassemble, Fig. 9

1. Place cover on press bed with pressure plate supported on ⅜" blocks or spacers. Place a bar across top of cover and apply pressure to compress clutch springs to relieve strain on yoke bolts.
2. Mark pressure plate and cover so parts can be assembled in original position. Remove three bolts and washers, then release press slowly. Remove bar from cover, lift off cover and remove springs.

Clutch Assemble

Reverse the disassembly procedure to reassemble the clutch. A small quantity of Lubriplate 320 should be applied on lever pin bearings and on driving lugs of pressure plate as these parts are assembled.

If pressure plate and/or center drive plate have been ground thinner, shims equal to the amount of material ground off must be installed under each pressure spring. Shims can be made to same diameters as insulator washers.

Release Levers Adjust

Using a special spacer plate or ground gauge blocks in place of center drive plate and driven discs, mount clutch cover on flywheel. Spacer plate or blocks must be 1.317" thick. When blocks are used, space them evenly under cover and use at least six of them.

With cover and flywheel bolts firmly tightened, measure distance from rear face of cover to crown of adjusting screws. Turn lever adjusting screws to obtain $\frac{11}{16}$" between top of screw to a straightedge held across cover.

When correct adjustment on all screws is obtained, remove cover and stake a portion of release lever at each side of screw while supporting screw head on solid metal surface.

Clutch Install

1. Apply a small amount of lubricant on pilot bearing. Apply Lubriplate 320 sparingly to drive lugs on center drive plate.
2. Place front driven disc, center drive plate and rear driven disc at flywheel.
3. Insert a suitable aligning arbor through driven discs and into pilot bearing to properly locate driven discs.
4. Locate pressure plate and cover on flywheel with alignment marks (made during removal) indexed. Start two cover bolts with lock washers at top where there is sufficient clearance to allow use of wrench. Turn flywheel to bring another pair of cover bolt holes to top and start screws. Do not fully tighten bolts until all have been started.
5. As cover bolts are tightened, try withdrawing aligning arbor from time to time to assure free fit of arbor in driven disc splines.
6. Complete installation and adjust clutch linkage.

Manual Shift Transmission Section

For Clark, Fuller, New Process, Spicer and Warner transmissions used on GMC trucks, see the "name" chapter for service procedures and lubricant capacities

TRANSMISSION, REPLACE

3-Speed

1. Remove transmission rear support (if used) and disconnect propeller shaft from transmission.
2. Disconnect transmission control rods from levers at transmission.
3. Disconnect speedometer shaft at rear of transmission case.
4. Remove clutch housing underpan to gain access to the transmission lower mounting bolts.
5. Remove upper and lower mounting bolts, replacing guide pins in the upper holes.
6. Pull transmission straight back and out.
7. Install in the reverse order, using guide pins in the upper mounting holes to keep the transmission in alignment with the clutch housing during installation.

4 & 5 Speed Light & Medium Duty

1. Remove access cover from cab floor.
2. On C.O.E. models, remove bellows and transmission control tower.
3. Disconnect speedometer shaft at rear of transmission case.
4. Disconnect transmission rear support (if used).
5. Disconnect propeller shaft.
6. On conventional models, remove hand brake lever and linkage at transmission.

Fig. 1 GMC light duty three-speed transmission. 1952-54

7. Disconnect transmission strut rod (if used).
8. Remove clutch housing underpan.
9. Remove the two top transmission mounting bolts and replace with guide pins.
10. Remove lower mounting bolts.
11. With jack under transmission, move unit straight back and out.
12. Install in reverse order.

All Heavy Duty

The procedure to remove the transmission from the above model trucks is dependent generally upon the type of cab, type of body, and lifting equipment available in the shop. Operations other than those included in this procedure may be necessary if the vehicle has special equipment such as power take-off and controls.

The required operations will be obvious upon visual inspection of the vehicle. Therefore, the following instructions should be used as a guide in replacing a transmission.

1. Inside cab, remove seals and/or cover plates from floor above transmission.
2. If gearshift lever tower is removable, remove it. Some C.O.E. models have the gearshift lever clamped to a stub lever at the transmission cover. In such instances gearshift lever may be removed from stub lever instead of removing the complete tower assembly.
3. Remove hand brake lever and bracket when those items are mounted on the transmission cover. On some models it is necessary to detach the auxiliary transmission control lever bracket which is mounted on the main transmission.
4. Disconnect propeller shaft at flange at rear of transmission. If a separate auxiliary transmission is used, it may be necessary to remove the complete propeller shaft between the transmission and auxiliary unit to provide sufficient clearance to move transmission away from engine. On long wheelbase trucks with propeller shaft center bearing, remove center bearing bolts to allow movement of propeller shafts to provide clearance.
5. Disconnect clutch control linkage and, except when an auxiliary transmission is used, disconnect speedometer cable housing from connector on mainshaft rear bearing cap. Disconnect engine ground strap if attached to transmission case or clutch housing.
6. Disconnect strut rod from rear of transmission.
7. Drain lubricant from transmission and if power take-off is used, remove unit and controls.
8. Inspect to determine if other equipment or brackets must be removed to permit removal of transmission. On some trucks the exhaust pipe or support brackets must be removed.
9. *On trucks equipped with Fuller transmissions, the air pressure must be exhausted from the air system and the air line must be disconnected from the pressure regulator valve before transmission can be removed. Also the feed wire to the circuit switch must be disconnected.*
10. Place transmission dolly or jack under transmission and adjust to carry weight of transmission. Then remove the rear support (if used). If there is sufficient clearance, the rear support may remain on transmission during removal. However, it will be necessary to disconnect support from brackets at frame
11. Remove bolts which attach clutch housing to flywheel housing and move transmission straight back from the engine, using care to keep the main drive gear shaft in alignment with the clutch disc hub.
12. If the transmission is to be disassembled, remove the clutch release mechanism and remove the hand brake mechanism and rear support members if these parts are installed at the rear of the transmission.
13. Reverse the foregoing procedure to install the transmission.

GMC 3 SPEED LIGHT DUTY UNIT, 1952-54

Disassemble

To disassemble the transmission, refer to Figs. 1 and 2 and proceed as follows:

1. Remove cover and shifter assembly.
2. Place transmission in two gears at once to lock the mainshaft and remove the universal joint or yoke retaining cap screw and lockwasher. Slide yoke off mainshaft.
3. Remove clutch gear retainer.
4. Install special clutch gear and bearing puller, Fig. 3, by screwing the threaded sleeve (left-hand thread) on the clutch gear shaft. Turning the puller handle will remove the gear and bearing without damage to the mainshaft pilot bearing.
5. Remove the two groups of roller bearings (14 and 24) from inside of clutch gear.
6. Remove hex head pipe plug from top of rear bearing retainer. On ¾ ton models, remove four capscrews retaining, rear bearing support to housing. Using a hook type puller, pull transmission rear bearing support out of rear of transmission housing.
7. Remove universal joint spacer, speedometer drive gear and drive gear spacer. On ¾ ton models an oil slinger is mounted between the spacer and the universal joint.
8. Turn the yoke of the mainshaft removing and replacing tool, Fig. 4, back on the threads and screw the adapter on the puller shaft, then install the puller shaft into the threaded end of the mainshaft. Bolt the yoke of the tool to the transmission case. *Turn front synchronizer ring so that the lugs line up with the slots in the mainshaft helical spline.*

Fig. 3 Removing main drive gear and bearing with puller

Fig. 2 GMC light duty three-speed transmission. 1952-54

9. While holding puller shaft handle, turn puller handle clockwise to force the mainshaft out of the rear bearing. Disassemble the puller from the mainshaft and the transmission case and remove mainshaft from transmission through front of case.
10. Shift second speed gear into clutch sleeve. Remove clutch sleeve assembly, first and reverse sliding gear and second speed gear from case as a unit. Remove second speed gear thrust washer from case.
11. Expand rear bearing lock ring into case, Fig. 5, with the special expanding tool shown. This raises the lock ring from the groove in the bearing and the bearing may be removed by lightly tapping the outer race toward the inside of the case. *It is necessary to remove the rear bearing before attempting to remove the countergear.*
12. Remove the countershaft by driving from the rear to the front of the case, using a brass drift. Remove the countergear, and the front and rear thrust washers and needle bearings from the bottom of the case. *It is necessary to remove the countergear before removing the reverse idler shaft, otherwise the idler shaft will strike the countergear.*
13. Drive out the reverse idler shaft expanding plug from inside of the case. A hook-nosed punch or drift will be found most suitable for this job.
14. Drive the idler shaft lock pin into the shaft. *This pin is shorter in length than the diameter of the shaft so that the shaft may be slipped out when the pin is driven in. Do not turn the shaft while removing as the lock pin may drop down between the idler shaft bushings.*
15. Remove reverse idler shaft and thrust washer.

Clutch Gear Bearing, Replace

Mount the clutch gear in a vise and remove the bearing retainer nut and oil slinger, using a spanner wrench of the type shown in Fig. 6. The retaining nut and oil slinger is a one piece steel casting

Fig. 4 Removing mainshaft with puller

Fig. 5 Removing mainshaft rear bearing by expanding lock ring with tool as shown

Fig. 6 Removing clutch gear retaining ring and oil slinger

Fig. 7 Removing synchronizer ring by expanding lock ring

machined with a left-hand thread and is locked in place on the clutch gear shaft by being staked in the hole provided for that purpose.

Mount the gear and bearing on an arbor press and press the shaft out of the bearing.

Clutch Sleeve, Disassembly

1. Remove the second speed gear.
2. Remove sliding gear.
3. Turn synchronizer ring in clutch sleeve until ends of ring retainer can be seen through slot in clutch sleeve.
4. Using snap ring pliers, expand retainer into counterbore in clutch sleeve, Fig. 7, and slip out the ring.
5. Check synchronizer cones for wear or for being loose in clutch sleeve. If cones are damaged in any way, it will be necessary to replace the clutch sleeve assembly and both synchronizer rings.

Synchronizer Rings

Inspect the synchronizer rings for smoothness. Place the synchronizer rings in the cones and check with thumbs to see that rings do not rock. Excessive rocking indicates a poor fit between the rings and cone, which will not permit proper synchronizing of gears during shifting.

Synchronizer Energizing Spring

When examining these springs, notice that one of the ends is slightly offset. Each spring must be assembled in its groove in the clutch gear and second speed gear with the offset or locking end between the third and fourth teeth of either of the two banks of teeth on these gears, thus keeping the spring from turning in its groove.

Under normal operation it should never be necessary to replace the energizing springs. However, should an energizing spring be removed for any reason, a new spring should be installed. The spring may be removed by slipping a thin blade under the spring and raising it sufficiently to slide it off over the clutch gear teeth. *In replacing either spring, be careful not to distort the spring when expanding it over the clutch teeth.*

Reverse Idler Gear Bushings

The bushings used in the idler gear are pressed into the gear and peened into holes in the bores to lock them in place, and are accurately bored with special diamond boring tools. This insures the positive alignment of the bushings and the gears. Because of the high degree of their shafts as well as proper meshings of accuracy to which these parts are machined, the bushings are not serviced separately.

Check bushings for excessive wear by using a narrow feeler gauge between the shaft and bushing. The proper clearance is from .002″ to .004″.

Assembly Notes

1. When installing the reverse idler gear and shaft, make sure that the lock pin hole in the shaft lines up with the hole in the case at the same angle, Fig. 8.
2. Use a new idler shaft lock pin, coat the pin with Permatex and drive it in approximately $\frac{1}{16}$″ beyond flush with the case. Peen the hole slightly. The lock pin must be a tight fit in the case to prevent oil leaks.
3. Install a new idler shaft expansion plug in the case.
4. The flat on the forward end of the countershaft engages the clutch housing when the transmission is installed in the chassis and keeps the countershaft from turning. This flat must be horizontal and at the top or the transmission cannot be assembled to the clutch housing.
5. When installing the mainshaft rear bearing, first install the lock ring in the case. Start the bearing in from the rear, making sure the wide side is to the front of the case and use the lock ring expanding tool (see Fig. 5) to expand the ring in the case.
6. Using a brass drift, tap the bearing on the outer race until it passes inside the lock ring. Then remove the lock ring expanding tool and continue to tap the bearing until the lock ring seats in the bearing groove.
7. For initial lubrication, coat the second speed bearing area of the mainshaft with lubricant. And when installing the mainshaft, the lugs on the front synchronizer must slide through the slots in the mainshaft spline. Push the shaft into the clutch sleeve as far as possible by hand, picking up the second speed gear and thrust washer.
8. The proper seating of the mainshaft may be determined by checking the end play of the second speed gear which should be approximately .010″.

Fig. 8 Reverse idler shaft, gear and lock pin

Universal Joint Ball, Adjust

Due to the construction of the universal ball joint on the ½ ton truck, it is important that proper adjustment be made at this point. This type joint, if improperly adjusted, may result in oil leakage if too loose, or transmission noise if too tight.

Whenever the universal joint is split for any service operation, or should a leak develop at this point, the adjustment should be performed with the ball joint collar oil seal (cork) removed. Attempted adjustment with this cork seal in place, whether it be a new or old seal, will give a false adjustment.

1. Remove universal joint ball from torque tube.
2. Wash universal ball thoroughly in cleaning solvent, then inspect it for roughness. If ball is rough, smooth up with fine emery paper, or if deeply scored, replace.
3. Using four new universal ball collar shims as a starting point, install universal ball and collar. Tighten attaching bolts 8 to 12 lb. ft. torque. *Do not install cork oil seal at this time.*
4. With attaching bolts tight, place both hands on the universal ball or on the housing assembly close to the ball. If the assembly can be moved and is a snug fit, the torque ball is properly adjusted. If the ball or housing cannot be moved by hand or is too loose, remove the ball collar attaching bolts and remove shims to tighten or add shims to loosen until proper adjustment is secured.
5. Remove universal ball or housing assembly, noting number of shims used for later assembly.

GMC 3 SPEED LIGHT DUTY UNIT, 1958-63

Disassemble

1. Remove side cover and gasket (refer to Figs. 9 and 10).
2. Remove main drive gear bearing retainer and, with the puller shown in

Fig. 3, remove the main drive gear and bearing.

3. Remove 24 roller rear pilot bearings, 2 washers and 14 roller front bearings.
4. Unfasten extension housing from transmission case and pull extension and mainshaft out of transmission case, leaving the synchronizer and first and reverse gear in case.
5. Remove synchronizer clutch sleeve and first and reverse gear through side opening in case.
6. Remove countershaft by driving it from front to rear of case, using a soft steel drift. Remove the countergear rollers and thrust washers.
7. Remove the countergear.
8. Drive the idler shaft lock pin into the shaft. This pin is shorter than the diameter of the shaft so the shaft may be slipped out when the pin is driven in.
9. Using a drift pin, tap rear of idler shaft to drive out plug ahead of shaft. Do not turn the shaft while removing as the lock pin may drop down between the idler gear bushings.
10. Remove reverse idler gear and thrust washers.
11. To remove the mainshaft from the extension, expand the bearing snap ring and tap the rear of the shaft with a soft hammer to bring the shaft, speedometer drive gear, second speed gear and bearing out of the extension as an assembly.

Mainshaft, Disassemble

1. Press speedometer gear off mainshaft, using suitable split plates in an arbor press.
2. Remove bearing-to-mainshaft snap ring and press bearing off shaft.
3. Remove second speed gear thrust washer, pull drive pin out of shaft and remove second speed gear.

Mainshaft, Assemble

1. Slide second speed gear on mainshaft, insert drive pin in shaft and install thrust washer against gear.
2. Install new bearing with groove in outside diameter of bearing toward second speed gear.
3. Select one of four available snap rings so end play of bearing on shaft is a maximum of .004″. This may be determined by installing successively larger rings. Use the thickest ring that will enter snap ring groove on shaft.
4. Start speedometer drive gear on shaft with chamfered inside diameter of gear toward bearing. Press gear on shaft until forward face of gear is ⅞″ from rear face of bearing.

Service Note

Service on the main drive gear bearing, clutch sleeve and synchronizer, reverse idler gear bushings and installation of the countergear and needle bearings is the same as for 1954 units.

Reassemble the transmission in the reverse order of disassembly, observing the precautions outlined in the assembly notes for 1954 insofar as they apply to the 1955 unit.

Fig. 9 GMC light duty three-speed transmission. 1955-63

Fig. 10 GMC light duty three-speed transmission. 1955-63

GMC 4 SPEED UNIT

Synchromesh, 1952-63

Disassemble

1. Refer to Figs. 11 and 12 and remove transmission cover.
2. Remove reverse shifter lever bolt nut, screw bolt out of case and remove reverse shifter lever, spacer and flat washer.
3. Remove clutch gear bearing retainer and gasket and, with a puller, pull clutch gear from case. *Index cut-out section of clutch gear with countershaft driven gear to obtain clearance in removing clutch gear and shaft.*
4. Remove clutch gear synchronizer cone and transmission mainshaft pilot bearing roller spacer from end of mainshaft.
5. Remove speedometer driven gear from rear bearing retainer.
6. Place transmission in two gears at once to lock gears and remove universal joint flange retaining screw, lockwasher, plain washer and universal joint front flange.
7. Remove rear bearing retainer and gasket.
8. To remove mainshaft assembly the entire assembly must be pulled back to remove rear mainshaft bearing from case. Use a suitable puller (tool No. J-2667) to pull shaft and bearing out of case.
9. Remove puller from case and then move mainshaft back as far as it will go.

Fig. 11 GMC four-speed synchromesh transmission. 1952-63

10. Use suitable puller (tool J-1619) to remove rear bearing from mainshaft.
11. With first and second speed sliding gear forward, raise front end up and lift shaft out of case.
12. To remove reverse idler gear, drive out shaft retaining pin, using a small punch. This pin is driven into the shaft, after which the shaft may be driven out of the case from front to rear. With shaft removed, take reverse idler gear from case.
13. To remove countershaft assembly, drive a punch through the countershaft front bearing spacer and pry out spacer.
14. Drive countershaft to the rear of the case, using a brass drift on the front end of the shaft, until rear bearing is driven out of case.
15. Remove rear bearing retainer bolt lock plate, retainer bolts and retainer.
16. Using a suitable bearing puller, remove rear bearing and oil deflector from rear end of countershaft.
17. Raise front end of countershaft and lift assembly from case.
18. Remove transmission chip collector from bottom of transmission case.

Clutch Gear

Remove mainshaft pilot bearing rollers from clutch gear and take roller retainer from recess in shaft. Place clutch shaft in a vise and, with a suitable spanner wrench(tool J-2670), remove bearing retaining nut, oil slinger and oil deflector. Use an arbor press to press gear and shaft out of bearing.

To assemble, press bearing on shaft. Then install oil deflector, oil slinger and retaining nut, noting that nut is designed to fit contour of oil slinger. When installing foregoing parts, make sure oil deflector centers around retainer nut hub. Place clutch shaft in vise and tighten retainer nut securely and stake in place. Apply a small amount of grease to bearing surfaces in shaft recess. Install 18 pilot bearing rollers and roller retainer. This retainer holds bearings in position and when transmission is assembled it is pushed forward into recess by mainshaft pilot.

Mainshaft, Disassemble

1. Remove clutch hub retainer ring from pilot end of mainshaft.
2. Support assembly on sliding gear in arbor press and press mainshaft out of gear cluster.
3. Remove clutch key springs from third and fourth speed clutch hub and remove sleeve from hub, being sure to account for three clutch keys.
4. Remove synchronizer cone from third speed gear.
5. Remove bushing from third speed gear and remove gear. *Second speed thrust washer goes between third and second speed gears.*
6. Remove second speed gear from synchronizer ring lugs.
7. Remove synchronizer ring retainer and synchronizer from first speed gear.

Mainshaft, Inspect

After washing all parts, proceed as follows:

1. Inspect mainshaft for scoring or excessive wear at thrust surfaces or splines.
2. Inspect clutch hub and sleeve for excessive wear and make sure sleeve slides freely on clutch hub. Also check fit of clutch hub on mainshaft splines. The third and fourth speed clutch sleeve should slide freely on the clutch hub but the clutch hub should be a snug fit on the mainshaft splines.
3. Inspect third speed gear thrust surfaces for excessive scoring and third speed gear bushing for excessive wear. The third speed gear must be a running fit on the mainshaft bushing and the bushing should be a press fit on the shaft.
4. Check second speed thrust washer for excessive scoring.
5. Inspect second speed gear for excessive wear at the thrust face or in the bronze bushing. Check synchronizer springs for looseness or breakage. Synchronizer springs may be replaced by removing the rivets and installing a new spring with new special rivets. If bushing is worn excessively, the gear assembly must be replaced.
6. Inspect second speed gear synchronizing ring for excessive wear.
7. Inspect bronze synchronizer cone in first speed gear for excessive wear or damage. Also inspect clutch gear synchronizer cone and third speed gear synchronizer cone for excessive wear or damage.
8. First speed sliding gear must be a sliding fit on mainshaft splines.
9. Inspect all gear teeth for excessive wear.

Mainshaft, Assemble

1. Install second speed gear synchronizing ring into first speed gear and install synchronizing ring retainer. Make sure ring retainer is seated fully in snap ring groove of first speed gear, Figs. 13 and 14.
2. Install first speed sliding gear on mainshaft splines with synchronizing ring toward front of shaft.
3. Install second speed gear on shaft with synchronizer springs toward synchronizing ring in first speed gear. Position gear so two cut-out sections index with prongs on synchronizing ring.
4. Install second speed gear thrust washer.
5. Install third speed gear bushing on mainshaft until it bottoms on second gear thrust washer.
6. Check second speed gear end play which should be .009″ to .015″.
7. Install third speed gear over mainshaft bushing and place synchronizing cone on taper of third speed gear.
8. Install clutch sleeve over clutch hub with taper toward long shoulder on hub and drop the three clutch keys into position. Install clutch key springs, one on each side of clutch hub, making sure springs fit under the clutch keys to hold them out against clutch sleeve. Both springs must be installed in the same relative position to provide even tension on the clutch keys.
9. Support mainshaft assembly in an arbor press. Install clutch hub assembly with taper on clutch sleeve and long shoulder of clutch hub toward pilot on mainshaft. Then press clutch hub onto shaft until it bottoms. Make certain that slots in third speed gear synchronizing cone index with the three clutch keys in the clutch hub.

64. Countershaft front roller bearing
65. Countershaft assembly
66. Countershaft rear bearing oil deflector
67. Countershaft rear bearing
68. Countershaft rear bearing retainer
69. Lock plate

10. Check third speed gear end play which should be .010″ to .014″.
11. Install clutch hub retainer ring. The retainer ring is a selective lock ring and should be checked carefully for proper thickness at assembly. There are four thickness rings available.

Countershaft Gears, Replace

Should it be necessary to replace any of the countershaft gears, the lock ring on the front end of the shaft should first be removed and then the assembly supported on an arbor press and the shaft pressed out of the train of gears.

When reassembling the new gears to the countershaft, the radius end of the second speed gear faces the first speed gear. The third speed gear is installed next and inasmuch as both sides of this gear are identical it may be installed either way. The reverse speed gear is installed onto the shaft next so that the chamfered end of the teeth face the counter driven gear. Only one spacer is used and that is installed between the reverse gear and counter driven gear. The counter driven gear is installed last.

When pressing the gears on the countershaft, new drive pins should be used and, after all gears are pressed into position, the round pins should be driven $\frac{1}{32}$″ below flush with shoulder on counter driven gear hub. The snap ring on the front end of the countershaft is a selective lock ring and should be checked carefully for proper thickness on assembly.

Fig. 13 Details of 3rd and 4th speed synchronizer parts

Fig. 14 Details of 2nd speed synchronizer parts

Reverse Idler Gear Bushings

If new bushings are required, press them into the gear from each end until flush with ends of gear. It is important that these bushings be staked as they are split bushings and may have a tendency to creep if not properly staked. When installed and properly staked, they must be line-reamed to size.

Transmission, Assemble

1. Install chip collector in bottom of case.
2. Assemble countergear front bearing spacer into case with its open side toward the outside and its edge flush with case.
3. Install countershaft assembly with rear bearing hub extending through rear bearing hole in case.
4. Install oil deflector and rear bearing on countershaft, using bearing retainer to drive bearing onto shaft. Lock bolts by bending tangs on lock plate.
5. Move countershaft forward into position. Rear bearing outer snap ring limits forward movement of countershaft.
6. Place reverse idler gear into position and install shaft from rear to front, being careful to have slot in shaft in a horizontal position.
7. Drive idler shaft in until hole in shaft aligns with lock pin hole in case and install lock pin.
8. Install mainshaft so that rear of shaft protrudes out of rear bearing hole in case.
9. Install mainshaft rear bearing onto shaft.
10. Install mainshaft pilot bearing spacer on mainshaft pilot. Then install clutch gear synchronizer cone to pilot end of mainshaft and move mainshaft forward until clutch sleeve clears third speed gear on countershaft assembly.
11. Index cut-out portion of clutch gear teeth to obtain clearance over countershaft driven gear and install clutch gear assembly into case.
12. Install clutch gear bearing retainer, using new gasket. Apply Permatex or other suitable sealing compound to bearing retainer bolt threads, install bolts and tighten to 15-18 foot pounds.
13. Raise front end of mainshaft and enter pilot into mainshaft pilot rollers in clutch gear.
14. Using suitable pusher tool (J-2667) install mainshaft and bearing into case. Make sure three cut-out sections of fourth speed synchronizer cone align with three clutch keys in clutch assembly.
15. Install rear bearing retainer, using new gasket. Apply Permatex or other suitable sealer to retainer bolt threads and tighten bolts to 20-25 lb. ft. torque.
16. Place reverse shifter lever into position and thread lever bolt with bolt sleeve and flat washer through lever and into case from inside out. Tighten bolt to 25-30 lb. ft. torque. Install shift lever bolt nut and tighten to 60-65 lb. ft. torque. The sleeve is used under the head of the bolt to act as a shoulder for shifter lever to pivot on.
17. Install universal joint flange with speedometer drive gear on mainshaft. Lock transmission in two gears and tighten yoke retaining cap screw to 60-65 lb. ft. torque. Install speedometer driven gear in rear bearing retainer and tighten securely.
18. Make sure all transmission gears are in neutral and, using a new gasket, install cover assembly, being sure shifting yokes slide over their proper gears and that reverse shifter lever engages the reverse shifter head. Install cover attaching screws and tighten to 20-25 lb. ft. torque.
19. Check operation of transmission in all gears to be sure there is no indication of binding in any position.

Hydra-Matic Transmission Section

For service procedures on the Hydramatic transmission, see the Hydramatic Transmission chapter

HYDRA-MATIC LINKAGE

Before making any checks or adjustments of the transmission linkage, check the performance of the engine. The transmission is often blamed for poor operation of the vehicle when the engine is not tuned to deliver maximum power.

Fig. 1 is a drawing showing a typical linkage hook-up. There are so many linkage variations and intricate hook-ups that it is impractical to illustrate and go into specific procedures for each one. However, there are only two things to remember when it becomes necessary to adjust the linkage:

1. Throttle linkage must be adjusted so that when the carburetor throttle valve (or valves) is fully closed (hot idle) the transmission throttle valve lever must be all the way toward the rear of the transmission against its internal stop.
2. Manual linkage must be so adjusted

Fig. 2 Checking throttle lever position with gauge

Fig. 3 Use of tool for bending throttle lever

Fig. 1 Schematic drawing of a typical Hydra-Matic linkage hook-up

that the hand lever can be moved freely through all positions of the shift quadrant (from Neutral to Dr) and that the pointer is directly over the positions as they are selected.

Throttle Linkage

Before adjusting the throttle linkage it is advisable to check the alignment of the throttle lever with the throttle rod, Fig. 1. If the alignment is incorrect, bunched shifts, slippage and rough shifting can result.

There are a number of gauges made especially for this operation, one of which is shown in Fig. 2. If an adjustment cannot be made, that is, if the throttle rod cannot be lengthened or shortened to cause the carburetor throttle valve to be fully closed while the transmission throttle lever is all the way back against its stop, bend the throttle lever as required to obtain the desired result. Fig. 3 illustrates one type of bending tool made especially for this purpose. A tool of this type will successfully bend the throttle lever without causing internal damage to the transmission.

To make the adjustment, first disconnect the throttle linkage at the carburetor to relieve all tension from the rest of the linkage. Then disconnect the throttle rod from the throttle lever at the transmission. Hold the throttle lever back against its stop and adjust the throttle rod clevis or trunnion (whichever is used) so that the throttle rod can be attached to the throttle lever without moving the lever away from its stop. The throttle linkage at the carburetor can then be adjusted so that the carburetor throttle valve is fully closed (hot idle).

If a road test indicates that the shifts occur too early, shorten the rod a turn or two. If the shifts occur late lengthen the rod a turn or two. Again road test and, if necessary, alter the adjustment as required to obtain the desired result.

Manual Control Linkage, Adjust

1. Remove manual shift control rod from transmission outer lever.
2. At front end of manual shift control rod, turn both lock nuts away from trunnion.
3. Place transmission outer shift lever in "1-3" position (3rd detent from rear).
4. Place transmission selector lever against stop in "1-3" position.
5. Connect shift rod to transmission lever and lock.
6. At forward end of shift control rod, turn rear lock nut forward against trunnion finger tight. Then turn it one additional full turn. Lock the adjustment with the front lock nut.

Neutral Safety Switch, Adjust

To check the operation of the neutral safety switch, pull the secondary wire out of the center socket of the distributor cap. Place transmission selector lever in "1-4" position. If the starter operates when the ignition is turned on, adjust as follows:

Set hand brake and place selector lever in "1-4" position. Loosen safety switch bracket clamp screw. Adjust the switch bracket to a position where the starter will operate *only* when the selector lever is in neutral position. Tighten bracket clamp screw.

Rear Axle Section

For Eaton and Timken (Rockwell) driving axles used on GMC trucks, see the "name" chapters for service procedures and lubricant capacities

GMC 1952-54

Semi-Floating Axle

This rear axle is the semi-floating type. The drive pinion is splined and pressed in the propeller shaft, and end movement is prevented by a pin riveted through the shaft coupling and propeller shaft.

The double row pinion bearing is built with no looseness or end play. If there is any looseness between the bearing race and cone, it is probably caused by abrasive matter in the lubricant which wore down the balls.

The threaded nut type of differential bearing adjustment is used.

Axle Shaft, Remove

1. Remove wheel and brake drum.
2. Drain lubricant from differential and remove housing cover.
3. Remove differential pinion shaft lock screw, differential pinion shaft, axle shaft spacer (or thrust block) and differential pinions, Fig. 2.
4. Push axle shafts in toward the center of the axle and remove the "C" washers from inner ends of axle shafts.
5. Remove shafts from axle housing.

Axle Shaft, Install

1. Install gasket to flange, aligning center of three holes closest together with notch in flange. Apply heavy shellac or paint to both sides of gasket and oil deflector.
2. Install oil deflector over gasket, aligning oil pocket with notch in flange.
3. Insert six special bolts and force heads down to the deflector.
4. Peen end of shoulder on bolts into countersink around bolt holes in flange.
5. Inspect leather seal on inside of axle housing for excessive wear, damage or misplacement.
6. Slide axle shaft into place. *Use care to see that axle shaft splines do not cut leather oil seal.*
7. Place "C" washers on inner end of axle shaft. Pry shafts apart so that "C" washers are seated in counterbore in differential side gears.
8. Install differential pinions.
9. Select axle shaft spacer to give a free fit to .014" maximum clearance between ends of axle shaft and spacer, Fig. 3. *There are three sizes of axle shaft spacers available to establish this clearance.*
10. Install spacer and assemble pinion shaft, locking in place with special screw.
11. Replace axle housing cover with new gasket and refill differential.
12. Install brake drum. Make sure lug in web section of drum is aligned and extends into drain hole in axle shaft flange.

Axle Shaft Bearing, Replace

1. Remove axle shafts as outlined above.
2. Insert puller and remove bearing, retainer and oil seal, Fig. 4.
3. Inspect bore and dress out the old stake points as these stake points can cut a definite groove in the new seal, thus making a path for leakage of lubricant.
4. Place a light coat of Permatex No. 2 on the outside diameter of the new seal, being sure no sealing material gets on the leather lip of oil seal.
5. Using the tool shown in Fig. 5, place seal, bearing and inside bearing retainer on tool in that order.
6. Start bearing into axle housing and tap tool with hammer to seat parts.
7. Remove tool and stake oil seal in place with punch.
8. Install axle shafts.

Rear Axle, Replace

1. Remove wheels and brake drums.
2. Disconnect hand brake cables from cross shaft lever.
3. Disconnect hydraulic brake line from axle housing.
4. Disconnect shock absorber eye from anchor plate.
5. Remove spring "U" bolts and shock absorber attaching plate.
6. Disconnect spring shackles and drop springs.
7. Slide axle back to disconnect torque tube at front end and remove rear axle assembly from vehicle.
8. Reinstall the assembly in the reverse order of removal and bleed the hydraulic brake system.

Fig. 2 Removing axle shaft spacer or thrust block

Rear Axle, Disassemble

1. Drain lubricant and remove housing cover.
2. Remove axle shafts as outlined previously.
3. Unfasten torque tube from axle housing.
4. Remove differential bearing adjusting nuts and lift out differential.
5. Remove three tapered bearing retaining screws from axle housing and tap splined end of propeller shaft, allowing shaft to slide out.
6. Remove shims from inside propeller shaft housing, noting the number and total thickness of shims removed.

Propeller Shaft & Pinion, Disassemble

1. Drill end of rivet to clear countersink into which it is upset.
2. Drive out rivet.
3. Loosen pinion bearing lock nut and separate pinion from propeller shaft, using the equipment shown in Fig. 6. This joint is a light press fit.
4. Remove pinion bearing lock nut and press bearing from pinion shaft.
5. Remove bearing lock sleeve and rear bearing lock ring.
6. Remove rear bearing oil retainer and bearing.
7. Wash all parts and inspect for wear and damage. *Any end play in the double row bearing will allow the pinion to float in and out changing the pinion depth in the ring gear. Therefore, replace this bearing if any end play exists.*

Propeller Shaft & Pinion, Assemble

1. Install rear pinion bearing on pinion shaft and lock in place with lock ring.
2. Thread pinion oil retainer over shaft with bevel of large diameter of retainer towards pinion.
3. Coat beveled surface of bearing lock sleeve with rear axle lubricant and install on shaft with beveled edge toward pinion.
4. Press double row bearing on shaft with loading slots toward pinion

Fig. 4 Axle shaft bearing puller

Fig. 3 Checking clearance between axle shaft and spacer

Fig. 5 Axle shaft bearing and oil seal replacer

Fig. 6 Removing pinion from propeller shaft

Fig. 7 Installing pinion on propeller shaft

shoulder and install bearing lock nut.

5. Install splined end of pinion shaft into propeller shaft coupling and using the tool shown in Fig. 7, press pinion into coupling until rivet hole is aligned.
6. Install and rivet both ends of a new rivet.
7. Tighten bearing lock nut to 200-240 lb. ft. torque and lock in milled slot in pinion shaft.

Differential Bearing, Replace

1. Install bearing puller, Fig. 8, making sure puller legs are fitted securely in notches in case and see that retaining yoke is tight.
2. Tighten puller screw and remove bearing.
3. Install bearing as shown in Fig. 9.

Ring Gear, Replace

1. Remove ring gear bolts.
2. Tap ring gear off case.
3. Install guide pins in every other hole in ring gear, Fig. 10. These pins can be made from ⅜"-24x1½" long capscrews with heads cut off and ends slotted.
4. Make sure back face of ring gear and face of case are free of dirt and burrs and slip gear over pilot diameter of case.
5. Install every other ring gear bolt and lock washer. Draw them up evenly and snugly so ring gear face is flush with face of case.
6. Remove guide pins and install remaining bolts.
7. Tighten all bolts to 85-95 lb. ft. torque.

Differential Carrier, Assemble

1. If original ring gear and pinion are to be used, replace same thickness of shims in propeller shaft housing counterbore that were removed. *As a means of adjusting pinion depth, shims are available in thicknesses of .012, .015, .018 and .021".*
2. If a new ring gear and pinion are used, one .018" shim should be used as a standard starting point.
3. Install propeller shaft and pinion, driving it down until bearings are seated in housing, using the spacer (J-4050) shown in Fig. 11, to provide pinion to bearing clearance.
4. Check through bearing lock screw holes to make sure lock sleeve is in position against back of front pinion bearing.
5. Install three tapered lock screws and draw them down evenly and tightly, then tighten lock screw nuts.
6. Install differential assembly in carrier and install adjusting nuts. *Carefully slide adjusting nuts alongside the bearing so that threads on nuts fit into threads in carrier.*
7. Install bearing caps, aligning marks on cap with marks on carrier.
8. Install and tighten cap screws until lock washers just flatten out.

Ring Gear & Pinion, Adjust

1. Loosen right hand adjusting nut and tighten left hand adjusting nut, using differential adjusting wrench, Fig. 12, while turning ring gear. Continue tightening left hand nut until all lash is removed, then back off the left hand nut one notch to a locking position.
2. Tighten right hand nut to force left bearing firmly into contact with left adjusting nut. Then loosen the right nut and again tighten snugly against the bearing. This position may be easily determined as the nut comes

Fig. 8 Removing differential bearing

Fig. 9 Replacing differential bearings

Fig. 10 Use of guide pins when installing ring gear

Fig. 11 Checking pinion to bearing clearance

Fig. 13 Correct tooth contact

Fig. 14 High narrow contact. To correct, move pinion toward ring gear

Fig. 12 Adjusting ring gear and pinion

Fig. 15 Low narrow contact. To correct, move pinion away from ring gear

to a definite stop.

3. Tighten right hand nut a minimum of one additional notch to a maximum of two notches. If backlash is more than .008", loosen right hand nut and tighten left hand nut one notch. If backlash is less than .005", loosen left hand nut one notch and tighten right hand nut one notch.
4. Tighten bearing cap bolts to 115-135 lb. ft. torque. Recheck backlash and install both adjusting nut locks.

Ring Gear & Pinion Contact Pattern

Before installing the differential assembly into the rear axle housing, the tooth contact pattern should be checked. Allowable variations in the carrier or drive pinion will cause the pinion to be too far in or out even when shimmed properly. Thus, tooth contact must be tested and corrected as necessary or the gears may be noisy.

Paint the ring gear teeth with a light coating of red lead, white lead or prussian blue. Revolve the gears and observe the analyse contact, referring to Figs. 13 to 17.

Rear Axle, Assemble

1. Clean axle housing and place new gasket over carrier mounting bolts.
2. Install differential assembly in axle housing, install washers and nuts and tighten securely.
3. Lubricate hubs of differential side gears and install in differential case.
4. Install axle shafts as outlined previously.
5. Install housing cover and refill differential with approved type and quantity of lubricant.

GMC 1955-56
Semi-Floating Axle

This rear axle is of the semi-floating, hotchkiss drive type—torque tube not used. The drive pinion is of the over-hung type, mounted on preloaded taper roller bearings. Sealing the pinion shaft is accomplished at the front end by a spring-loaded leather seal bearing on the companion flange or rear universal joint rear yoke which is splined and bolted to the pinion shaft, Figs. 18, 19.

Axle Shaft, Remove

1. Remove wheels and brake drums.
2. Drain lubricant and remove housing cover.
3. Turn ring gear until pinion shaft lock screw can be reached. Remove lock screw and lock washers.
4. Remove pinion shaft and spacer (see Fig. 2).
5. Push each axle shaft in toward axle center; then remove lock from end of each shaft. Axle shafts may then be withdrawn from housing.

Bearing or Oil Seal, Replace

1. With slide hammer equipment, remove oil seal, bearing and bearing retainer.
2. Inspect and clean out housing bore and remove old stake marks. This is important as old stake points can cut groove in new seal, thus causing lubricant leaks.
3. When installing new seal, coat its outside with Permatex No. 2 or equivalent to prevent oil leak. Work soft, smooth grease into bearing rollers.
4. Install new seal, bearing and retainer.

Axle Shaft, Install

1. Note that the right shaft is longer than the left one.
2. Dip axle shaft splines in gear lubricant and insert shafts into housing. Support shafts to prevent damage to oil seals. Mesh end of shafts with side gear splines.
3. Install inner locks solidly in shaft grooves. Push shafts outward to seat inner locks fully in side gear counterbores.
4. Install pinions by placing between side gears and rolling them into place.
5. Select proper spacer by gauging be-

Fig. 16 Short toe contact. To correct, move ring gear away from pinion

Fig. 17 Short heel contact. To correct, move ring gear toward pinion

tween axle end and spacer as shown in Fig. 3. Clearance should be .003″ to .014″. Three sizes of spacers are available.

6. Insert pinion shaft through case, pinions and spacer. Align screw hole in shaft with hole in case. Install lock screw with lock washer.
7. Install housing cover, brake drums and wheels.

Rear Axle, Replace

Major operations on this axle assembly may be performed without removing the complete assembly from the vehicle. There may be occasions, however, when it will be necessary to remove the complete assembly as a result of collision which may cause distortion of axle housing or axle shaft tubes. *The following axle housing removal, therefore, is to be used only when replacement of axle housing is necessary.*

1. Raise vehicle from floor and support with stand jacks under frame side rails.
2. Remove rear wheels.
3. Remove two trunnion bearing "U" bolts from rear universal yoke and split rear universal joint. Tape bearings to trunnion.
4. Disconnect hand brake cable at equalizer and remove cables from clamps on frame.
5. Disconnect hydraulic brake line connection at rear axle housing.
6. Disconnect shock absorber eyes from anchor plates.
7. While supporting axle housing with hydraulic jack, remove spring "U" bolts and lower axle assembly to the floor.
8. Reverse the foregoing procedure to install the axle housing, being sure to bleed the brake system when the installation is completed.

Differential Carrier, Remove

1. Remove axle shaft as outlined previously. *Axle shafts may be pulled out only far enough to clear the differential side gears.*
2. Remove trunnion bearing "U" bolts from rear universal joint and split joint.
3. Lower propeller shaft to floor.
4. Remove nuts and copper washers that retain differential carrier to axle housing.
5. Place drip pan under carrier and slightly separate carrier and housing and allow lubricant to drain out.
6. Remove differential carrier assembly.

Differential Carrier, Disassemble

1. Referring to Fig. 21, mark bearing caps and carrier for reassembly in same position.
2. Remove differential bearing caps and adjusting nuts by tapping on bosses of caps until free from dowels. *Do not use screwdriver to pry caps off as this may damage machined face of caps.*
3. Remove differential and ring gear assembly from carrier housing.
4. Remove differential pinion shaft lock screw and differential pinion shaft from differential case.
5. Remove pinions and side gears.
6. Hold companion flange from turning with a suitable holding tool and remove propeller shaft flange nut.
7. Pull flange from pinion shaft.
8. Remove pinion from carrier by tapping on front end with soft hammer.
9. Remove pinion shaft oil seal, front bearing and bearing spacer from carrier. *Some axles may have a $\frac{1}{16}$″ shim behind the spacer. This is a production item only and should be discarded.*
10. Wash all parts and examine for wear or damage.

Fig. 19 Axle shaft mounting at outer end. For GMC Model H-033 axle

Fig. 18 Differential carrier assembly. GMC Model H-033

Pinion & Bearings, Replace

1. Using a brass drift, remove front and rear bearing outer races.
2. Install new bearing cups in carrier. Bearings seat against shoulders, Fig. 18.
3. Remove rear bearing inner cone. Note size of shim removed from between cone and gear.
4. Determine the correct shim to be placed between the pinion and rear pinion bearing inner race. This shim is installed with the three tangs toward the pinion gear face. If the original ring gear and pinion are being used in the original carrier, install the original shim or one the same size if the shim is damaged. *If a new pinion or differential carrier is being installed, note the markings on the end of the pinion gear and on the differential carrier and obtain the correct shim size to use with these parts from your supplier.*
5. Install new bearing cone, pressing cone against shim and rear face of pinion.

Ring Gear, Differential Bearings & Case, Replace

These parts are replaced in the same manner as outlined previously for the H-033 axle.

Differential, Assemble

1. Lubricate pinion bearings with hypoid lubricant and install pinion in carrier.
2. Install a new pinion bearing spacer with large end toward gear.
3. Install front pinion bearing cone on pinion shaft.

Fig. 21 Exploded view of differential carrier assembly. GMC Model H-033

4. Soak new oil seal for 10 minutes in light engine oil. Wipe outside diameter at seal and coat with a sealer such as Permatex No. 2. Install new seal with a suitable driver.
5. Install companion flange and deflector, securing with special washer and new special self-locking nut.
6. Check the pinion bearing preload with a torque wrench or with a spring scale. Tighten the flange nut until the torque required to turn the pinion with the torque wrench is 15-25 inch lbs. If a spring scale is used, it should require 1⅞ to 3⅛ lbs. to turn the pinion.
7. Install differential in carrier with outer races and adjusting nuts.
8. Install bearing caps, aligning marks on caps with marks on carrier.
9. Install and tighten cap nuts snugly.
10. Lubricate hubs of differential side gears and install in differential case.
11. Roll the differential pinions into position and install pinion shaft and lock screw.

Ring Gear & Pinion, Adjust

This procedure is preformed in the same manner as outlined previously for the 1954 H-033 axle.

Differential Carrier, Install

1. Clean axle housing and place new gasket over carrier mounting bolts.
2. Attach carrier assembly to axle housing, install new copper washers and nuts and tighten securely.
3. Connect rear universal joint.
4. Refill housing with approved type and quantity of lubricant.

GMC SINGLE SPEED

Full-Floating Axle

These rear axles, being of the full-floating type, enables easy removal of the axle shafts without removing the truck load or jacking up the rear axle.

The drive pinion is straddle mounted, being supported at the rear end by a straight roller bearing. On H-050 and H-072, Fig. 22, models, the drive pinion is supported by a tapered roller bearing composed of two inner cone and roller assemblies with a one-piece outer race for both bearings. On H-075, H-105, H-110, H-125 and H-130, Fig. 23, models, the drive pinion is supported at the front by a double-row ball bearing.

Axle Shaft, Replace

On H-050 and H-072 axles, Fig. 24, remove the bolts which attach the axle shaft flange to the wheel hub. Install two ½"-13 bolts in the threaded holes provided in the axle shaft flange. By turning these bolts alternately, the axle shaft may be easily started and then removed from the housing.

On H-075, H-105, H-110, H-125 and H-130 axles, after removing the hub cap, note the threaded hole in the center of the axle shaft flange. This hole is provided for use with a screw adapter which is to be attached to a hammer type puller. Screw the adapter in the flange and pull out the axle shaft.

Reverse the foregoing procedure to install the axle shaft. But on H-075, H-105, H-110, H-125 and H-130 axles, Fig. 25, it may be necessary to move the truck slightly in order to align the splines on the shaft with those in the wheel hub and differential side gears.

On H-050 and H-072 axles, to prevent lubricant leaking through the axle flange bolts, a small amount of Permatex should be applied to the bolt threads. Use care in the amount of sealer applied as in too heavy an application the sealer will be squeezed out as the bolt is installed and may get between the axle shaft flange and hub and thus destroy the sealing of the flange to the gasket.

Wheel Bearings, Remove

1. Raise truck and place on stand jacks.
2. Remove wheel and axle shaft.
3. Remove hub and drum.
4. Remove inner bearing and oil seal with a suitable puller.
5. To remove outer bearing, first tap outer race to relieve tension at snap ring, then remove snap ring.
6. On H-050 and H-072 axles, press outer bearing from hub.
7. On H-075, H-105, H-110, H-125 and H-130 axles, remove the bearings by driving on the axle shaft spacer, using an end cut off an old axle shaft. This will also bring out the inner race and roller assembly.

Replace & Adjust

Install the bearings and oil seal in the reverse order of removal. Then, while turning the wheel hub, tighten the adjusting nut tight, then back it off 45°. Turn the hub by hand to make sure it turns freely. Install the adjusting nut and lock. Install and tighten the lock nut and replace the axle shaft.

Rear Axle, Replace

1. Raise vehicle from floor and support

Fig. 22 Exploded view of differential carrier assembly. GMC Models H-050 and H-072

Fig. 23 Sectional view of differential carrier. GMC models H-075, H-105, H-110, H-125, H-130. This unit is similar to Fig. 22 except that ball bearings are used on the drive pinion

with stand jacks under frame side rails.
2. Remove rear wheels.
3. Remove two trunnion bearing "U" bolts from rear yoke and split rear universal joint. Tape bearings to trunnion.
4. Swing propeller shaft to one side and tie to frame side rail.
5. Disconnect hydraulic brake line connection at rear axle housing.
6. On H-050 and H-072 axles, disconnect hand brake cables from cross shaft levers and remove cables from clamps on frame.
7. On H-050 and H-072 axles, disconnect shock absorber links or eyes from anchor plates or anchor bracket.
8. On all models, while supporting axle assembly with hydraulic jack, remove spring "U" bolts and lower axle assembly to floor.
9. Reverse the foregoing procedure to install the axle assembly.

Service Note

The following operations may be performed without raising the truck or removing the axle assembly from the vehicle.

Differential Carrier, Remove

1. Drain lubricant, remove axle housing cover and axle shafts.
2. Remove two trunnion "U" bolts from rear yoke and split rear universal joint. Tape bearings to trunnion.
3. Swing propeller shaft to one side and tie to frame side rail.
4. Remove bolts which attach carrier to axle housing. Support carrier with floor jack and roll it from under truck.

Differential Carrier, Disassemble

1. Remove ring gear thrust pad.
2. Remove differential bearing caps and adjusting nuts by tapping on bosses of caps until free from dowels. *Do not use screwdriver to pry off cap as this may damage machined face of cap.*
3. Remove differential and ring gear from carrier housing.
4. Unfasten pinion bearing retainer from carrier.
5. Remove pinion from carrier, using a brass drift against the pilot end of the pinion shaft, if necessary.
6. On H-050 and H-072 axles, remove shims from inside of carrier housing, making note of the number and total thickness of shims removed.
7. Remove nut from pinion shaft.
8. Drive bearing retainer and flange from pinion shaft.

Pinion Oil Seal, Replace

Drive oil seal and packing from bearing retainer. Soak new seal and packing in engine oil to provide initial lubrication. Install felt packing in bottom of bearing retainer recess and press oil seal in place. Make sure open end of leather in oil seal is toward pinion bearing.

Pinion Bearing, Replace

1. Remove rear pinion bearing snap ring and press bearing from shaft.
2. Press front pinion bearing from shaft. *On H-050 and H-072 axles, the outer race, two inner race and roller assemblies and spacer should always be installed as a group as the spacer is pre-selected to give proper pinion bearing adjustment.*
3. On H-050 and H-072 axles, press one new inner race and roller assembly on the pinion shaft, using a 2″ pipe, applying pressure against the inner race. Large diameter of bearing race should be toward pinion. Place spacer and outer race on shaft and press on other inner roller. Small diameter of this race should be toward pinion.
4. On H-075, H-105, H-110, H-125 and H-130 axles, press new double row pinion bearing on shaft, using a piece of 2″ pipe, applying pressure to inner race. This bearing must be installed so that extended portion of inner race is toward the back of pinion gear teeth.
5. On all models, press rear pinion bearing on shaft, using driver to apply pressure to inner race. Chamfered side of inner race should be toward pinion.
6. Install lock ring.

Fig. 25 Splined hub and axle shaft parts. GMC Models H-075, H-105, H-110, H-125, H-130 axles

7. Position pinion bearing retainer over hub of drive flange.
8. Install spacer on pinion shaft (H-050 and H-072 axles). On all models, install drive flange and bearing retainer with washer and nut.
9. Tighten pinion shaft nut to a torque load of 160-280 lb. ft. Lock nut with cotter pin.

Differential, Disassemble

1. Check differential case to make sure two halves are marked so they may be reassembled in the same position.
2. Remove attaching bolts and separate case from cover and remove pinion gears, spider and side gears.
3. Tap back of ring gear with soft hammer to remove gear from case.
4. Pull off differential bearings.

Differential, Assemble

1. Install differential bearings.
2. Install two guide pins to ring gear diametrically opposite each other. These pins can be made from ½″-20 x 2″ capscrews with heads cut off and slotted for use of screwdriver.
3. Start guide pins through holes in case flange and tap ring gear on case.
4. Place differential pinions on spider. Then assemble side gears and pinions to left half or cover of differential.
5. Assemble right half to left half, being sure to line up marks on both halves.
6. Install ring gear bolts and washers and tighten evenly until ring gear is flush with case flange.
7. Remove guide pins and install remaining bolts. Then tighten all bolts to 85-95 lb. ft. torque.

Fig. 24 Exploded view of wheel hub. GMC Models H-050 and H-072 axles

Fig. 26 GMC two-speed axle

Differential Carrier, Assemble H-050 & H-072 Axles

To facilitate adjusting of pinion depth in the ring gear, there are four shims available for service use. They are .012, .015, .018 and .021″. If the original ring gear and pinion are to be used, it is advisable to replace the same thickness of shims in the carrier housing counterbore that were removed. If a new ring gear and pinion are used, one .015 and one .018″ shim should be used as a standard starting setup.

1. Grease shims and place against bearing outer race.
2. Place new gasket on pinion bearing retainer and press pinion into carrier to avoid damaging shims.
3. Install and tighten pinion bearing retainer bolts to 85-95 lb. ft. torque.
4. Place races over differential bearing rollers.
5. Install differential into carrier and install adjusting nuts.
6. Install differential bearing caps, making sure marks on caps line up with marks on carrier.
7. Install cap bolts and tighten them until lock washers just flatten out.

Differential Carrier, Assemble H-075, H-105, H-110, H-125 & H-130 Axles

1. Install differential bearings.
2. Assemble pinion to carrier with new gasket and tighten pinion bearing bolts securely.
3. Install differential assembly in carrier and install adjusting nuts.
4. Install differential bearing caps, making sure marks on caps line up with marks on carrier.
5. Install bearing cap bolts and tighten until lock washers just flatten out.

Ring Gear & Pinion, Adjust

This adjustment is accomplished in the same manner as outlined for 1954 ½ ton rear axle.

Ring Gear Thrust Pad, Adjust

Inspect the bronze tip of ring gear thrust pad and replace if worn. Install the thrust pad and tighten the screw until the bronze tip engages the back of the ring gear while rotating the gear. Back off the screw 1/12 of a turn and

tighten lock nut. Make sure the screw does not turn during the locking process. This adjustment provides .005 to .007" clearance between ring gear and thrust pad.

GMC 2 SPEED AXLE

This axle, Fig. 26, is a planetary type which is shifted by the driver as operating conditions require. Movement of the control valve shift lever causes the shift chamber at the axle housing to select the desired speed range. The axle shafts and differential carrier can be removed for repair without removing the axle assembly from the vehicle.

Disassemble

1. Remove axle shafts.
2. Place jack under carrier and remove carrier-to-housing cap screws.
3. Break carrier loose with mallet and work it out of housing.
4. Place carrier in repair stand.
5. Remove anchor from carrier.
6. Remove shifter assembly.
7. Drive out shifter yoke shaft.
8. Slide shifter yoke and sleeve to the left, removing sleeve and yoke from end of sun gear.
9. Remove differential bearing adjusting lock from each side.
10. Remove oil trough.
11. Remove thrust screw and pad.
12. Remove differential bearing caps and adjusters.
13. Remove differential and planet assembly from housing.
14. Mark ring gear and both halves of planetary support case by marking lines on case and gear.
15. Remove drive gear from planetary support case and cover.
16. Lift off planet support case.
17. Remove thrust washer used between planet cover and differential.

Fig. 27 Spicer semi-floating axle showing adjusting points

18. Remove sun gear and four planet gears.
19. Mark or tag all gears so they can be reassembled exactly as removed.
20. Separate differential case halves. Case halves and spider are stamped on all four sides with matching numbers to assist in assembly.
21. Remove side gears and thrust washers from each case half.
22. Remove differential side bearings.
23. Loosen bolts attaching pinion bearing oil seal retainer to carrier. As bolts are loosened they will contact deflector flange on U-joint flange.
24. Tap universal joint yoke with mallet, driving pinion, bearings, and retainer assembly gradually from carrier housing while continuing to loosen attaching bolts.
25. Remove shims from carrier housing and note the amount required in back of the double thrust bearing.
26. Remove rear pinion bearing from carrier housing.
27. Separate U-joint yoke from pinion.
28. Remove pinion bearing oil seal retainer and seal from yoke.
29. Press off double thrust bearing.

Reassembly

Before axle is reassembled, make sure that all oil passages are thoroughly clean. Apply a thin coating of differential lubricant to all thrust and bearing surfaces to prevent scoring of parts when vehicle is first placed in service.

Pinion Assembly

1. Press bearing inner race on pinion.
2. Press double row thrust bearing on pinion.
3. Install pinion rear bearing in differential carrier.
4. Install original shim pack in carrier. Grease shims thoroughly. If original ring gear and pinion are reinstalled, use shims that were removed. If new gears are used, start with one .015" and .018" shim (total .022").
5. Position retaining cap screws and lock washers in oil seal retainer and install retainer on propeller shaft yoke.
6. Install new washer and nut and tighten securely.
7. Install pinion assembly into carrier and tap on yoke nut until cap screws can be started. Tighten cap screws alternately and evenly until pinion assembly is in place.

Differential and Planetary Assembly

1. Assemble differential parts into planetary half of case, then place plain half of case over assembled parts. *Be sure that all parts are assembled as indicated by marks stamped or tagged at time of disassembly. Also see that side gear with longest hub is on bevel gear side.*
2. Fasten differential case halves and tighten securely.
3. Install bearing cones at planetary support case cover.
4. Place ring gear on wood blocks with gear teeth down and install several guide pins in ring gear bolt holes. Then position planetary case cover over guide pins with marks in alignment.
5. Place a thrust washer in planetary support case cover, then install the assembled differential in case cover.
6. Install the four planet gears on differential case with long hub of gears away from case.
7. Install large planetary support case over the assembled parts with marks in alignment.
8. Fasten two halves of planetary support case and bevel gear together.

Fig. 28 Prying differential from housing. Spicer axle

Differential and Planetary Installation

1. Locate bearing races on each side, then install differential and planetary assembly in differential carrier.
2. Install differential bearing adjusting nuts on each side. See that oil baffle is in place in right adjusting nut.
3. Install differential bearing adjusting caps and dowels at each side.
4. Install cap bolts and lock washers and tighten snugly or until bearing adjusting nuts can just be turned.

Ring Gear and Pinion Adjustment

1. Loosen right hand adjusting nut and tighten left hand adjusting nut.
2. Continue tightening left adjusting nut until all backlash between ring gear and pinion is removed.
3. Back off left adjusting nut approximately two notches to a point where notch in nut is aligned with lock.
4. Tighten right adjusting nut firmly to force differential and planet assembly in solid contact with left adjusting nut. Loosen right adjusting nut until it is free of its bearing, then retighten snugly against bearing. Tighten right nut from one to two notches more to a locking position. This method provides for the proper pre-load on the bearings.
5. Mount a dial indicator on the housing and check the backlash between ring gear and pinion which should be .005" to .008". Whenever backlash is more than .008", loosen right adjusting nut one notch and tighten left nut one notch. If backlash is less than .005", loosen left nut one nut and tighten right nut one notch. When backlash has been adjusted, tighten bearing cap bolts securely. Again check backlash and then install adjuster locks.

Fig. 29 Installing differential and bearing cups. Spicer axle

Checking Pinion Depth

1. Coat ring gear teeth lightly with red lead or prussian blue. Then turn the pinion several revolutions in both directions while applying pressure to ring gear to create a load.
2. Examine the pattern on the ring gear. If the pinion depth is correct, the tooth pattern will be centered on the pitch line and toward the toe of the ring gear (see the *Rear Axle Chapter* for explanation of tooth patterns).
3. If the pattern is below the pitch line the pinion is too deep and it will be necessary to remove the pinion and increase the shim thickness between the pinion bearing and differential carrier housing.
4. If the pattern is above the pitch line on the ring gear teeth, the pinion is too shallow and it will be necessary to decrease the shim thickness.
5. Checking the pinion depth will make some change in the backlash; therefore, it may be necessary to readjust the backlash.
6. Tighten the bearing cap screws, recheck backlash and install adjusting nut locks.
7. Install oil trough.

Ring Gear Thrust Pad Installation

1. Inspect the bronze tip on ring gear thrust pad and replace if worn.
2. Install thrust pad and tighten until pad contacts ring gear. Then back off 30° to obtain a clearance of .005″ to .007″. Tighten lock nut, making sure screw does not turn.

Shifter Assembly Installation

1. Install shifter yoke on sleeve and install assembled parts on sun gear.
2. Install shifter lever and shaft through adapter and housing, then into the shifter yoke, mating the two parts carefully to avoid damage to the splines. The shaft must be free to avoid binding when the shifter assembly is installed.
3. Position shift anchor at left of differential carrier with anchor knob in bushing and opposite end secured to bearing cap with cap screw and lock washer.

Differential Carrier Installation

1. With new gasket in place, place carrier on roller jack, using a suitable wood block as a support.
2. Use a long drift to align assembly and install it in axle housing.
3. Install and tighten cap screws securely.
4. Use new gasket and install electric shift units. (For service on the Electric shift unit, see the *Eaton Electric Shift section of the Rear Axles Chapter.)*

SPICER AXLE

Integral Housing Type

Inasmuch as the axle tubes are pressed into the differential carrier to form a one-piece housing, the rear axle assembly must be removed from the chassis when it becomes necessary to overhaul the unit.

Disassemble, Fig. 27

1. Remove axle shafts. Axle shafts may be pulled out only far enough to clear differential side gears.
2. Drain lubricant and remove rear cover.
3. Make sure differential side bearing caps and axle housing are marked, then remove the side bearing caps.
4. Pry differential from housing, Fig. 28.
5. Remove side bearing cups.
6. Pull off side bearing and adjusting shims, tagging the shims for identification on reassembly.
7. Unfasten ring gear from case.
8. Drive out differential pinion shaft pin and pull out the shaft, pinions and side gears.
9. Hold companion flange from turning and remove flange nut.
10. Pull flange from pinion shaft.
11. Remove pinion from carrier by tapping on front end with soft hammer.
12. Remove pinion shaft bearing oil seal and bearings from carrier, keeping separate the shim pack at each bearing.

Pinion & Bearings, Replace

If the original ring gear and pinion are being used in the original carrier, use the original shim packs at each bearing, Fig. 27. If a new pinion or differential carrier is installed, note the markings on the end of the pinion gear and on the differential carrier to obtain the correct thickness of shimming to be used with these parts from your supplier. The shims behind the rear bearing establish the correct pinion depth.

1. Press the rear pinion bearing cup in the housing with the proper thickness of shims. Press the rear pinion bearing on the shaft.
2. Install the front bearing cup and shims, and front bearing.
3. Install the companion flange and, while holding the flange from turning, tighten the nut to a torque load of 200-220 lb. ft.
4. Check the pinion bearing pre-load with a spring scale and heavy cord wrapped around the companion flange. Pull on the spring scale. The torque required to rotate the pinion is 10-30 inch lbs. If not within these limits, add or remove shims from behind the front bearing to obtain the proper pre-load.
5. Remove the companion flange and install a new oil seal (well soaked). Reinstall the companion flange and tighten the nut to a torque load of 200-220 lb. ft.

Fig. 30 Method of correcting backlash between ring gear and pinion. Spicer axle

Ring Gear, Replace

1. Install guide pins in every other hole in the ring gear. These pins can be made from 1½″ long capscrews with heads cut off and ends slotted.
2. Make sure back face of ring gear and face of case are free of dirt and burrs and slip gear over pilot diameter of case.
3. Install every other ring gear bolt. Draw them up evenly and snugly so ring gear face is flush with face of case.
4. Remove guide pins and install remaining bolts.

Differential Carrier, Assemble

The differential bearings are adjusted by shims, Fig. 27. These shims also establish the ring gear position with the pinion. Therefore, backlash must be checked whenever a bearing adjustment is made.

The correct bearing adjustment is one which will provide a .015-.020″ pinch fit when the differential unit is assembled into the carrier. To make the adjustment, install the bearing cones without shims and place the assembly in the housing with the bearing cups. Force the unit to one side and check the clearance between the bearing cup and differential case with a feeler gauge.

When the clearance is determined, select shims of this amount plus .015-.020″ extra to establish the proper pre-load.

Remove the differential bearings again and divide the shims into two packs of equal thickness and install on each side and replace the bearings. Reinstall the unit in the carrier. This operation is made easier by cocking the bearing cups slightly when the differential is placed in the housing and then tapping them lightly with a mallet, Fig. 29. However, when installing the differential in the housing, be sure the ring gear teeth mesh with the pinion teeth before tapping the bearings in place.

After the bearing cups are firmly in place, install the bearing caps. The bearing caps and gasket surface of the housing are marked with a horizontal numeral and on the other side by a vertical numeral. The position of the numerals should correspond when reinstalling the bearing caps.

Ring Gear & Pinion Backlash, Adjust

Mount a backlash gauge indicator on the carrier and start checking for the correct backlash between the ring gear and pinion. If the backlash is not within the limits of .004″ to .009″, it will be necessary to change the arrangement of the shims back of the bearings. Make corrections in backlash according to Fig. 30, bearing in mind that shims removed from one side must be installed on the opposite side so that the total shim thickness of the right and left side will remain unchanged, and the bearing adjustment undisturbed.

Gear Tooth Contact Pattern

Allowable variations in the carrier or drive pinion may cause the pinion to be too far in or out even when shimmed properly. Thus, the tooth contact must be tested and corrected as necessary or the gears may be noisy.

Paint the ring gear teeth with a light coating of red lead, white lead or prussian blue. Revolve the gears and observe the contact, referring to Figs. 13 to 17.

Air Suspension

DESCRIPTION

Models 550 to 860

The air suspension system, Fig. 1, basically is made up of air chambers, air bellows, height control valves, radius rods and shock absorbers. Suspension supports and air beams provide means of connecting the suspension system to the axles. Operation of the system is completely automatic, maintaining a constant ride-height regardless of load.

Air Chambers & Bellows

The tubular front axle has a two-compartment center section that provides a separate chamber for bellows at each end of the front axle. Two air beams act as separate chambers for the bellows directly beneath the frame side rails at each end of the rear axle.

Four air bellows are mounted at the front axle, two each under each frame side rail. Larger bellows are mounted at the rear axle also under the frame side rails. Two bellows are mounted at the single rear axle, four at tandem axles. These bellows are held at the top and bottom by bead rings.

Height Control Valves

Air pressure in the air chambers controls the spring rate. This pressure is automatically varied in proportion to vehicle load. Four height control valves, two at front axle and two at rear axle, maintain constant vehicle height for all load conditions. The valves operate independently, levelling the vehicle to compensate for an unevenly distributed load. Height control valve operating arms are connected to the axles by adjustable links.

Radius Rods

Radius rods at the front and rear axles transmit driving and braking forces from axle to frame. A lateral radius rod at each axle controls the lateral position of the axles under the vehicle. A stabilizer bar attached to the frame side rails and rear axle controls vehicle sway. All linkage is rubber mounted and needs no lubrication.

OPERATION

Compressed air, metered into the air suspension system by the height control valves, is taken from the air tank. The pressure regulating valve, however, allows removal of air from the tank only when pressure in the tank is above 65 psi. The height control valves are actuated by the relative movement between the frame and axles. As the frame settles toward the axles under increased load, valve arms linked to the axles are moved upward. As the arms operate the valves, a sufficient volume of air is admitted to each set of bellows to raise the frame to normal ride height.

The distance between the axle and frame will increase as load is removed. The height control valves, in this case, will exhaust air from the bellows in proportion to the decrease in load.

The height control valves are designed to operate only when the load is increased or decreased. These valves do not respond to rapid relative motion between axles and frame such as that caused by road irregularities.

Each air chamber with bellows attached forms a single compartment for compressed air. The bellows serve as a flexible connection between the frame and axles. Flexing of the air bellows results in alternate increase and decrease in the air volume within the compartment. This action absorbs road shocks in the same manner as an inflated rubber tire cushions shock caused by road roughness.

Shock absorbers are double-acting, aircraft type. Mounted at both ends of each axle, these shock absorbers control axle rebound and further cushion the ride. Radius rods maintain the position of each axle against lateral, longitudinal and torsional movement.

CAUTIONS

Working Clearance

Before work is done from a creeper under the vehicle, blocks should be placed

Fig. 1 Typical air suspension system

between the axle and frame to provide proper clearance and avoid possible injury.

Lifting Vehicle

When towing or using hoist do not raise truck and permit the axle to hang unsupported. Air pressure will be exhausted from the suspension system and the weight of the axle hanging on deflated bellows may damage bellows. To avoid possible damage, chain the axle to the frame.

Air Beams

Avoid drilling holes in the air beams or front axle center. Do not strike these parts with a heavy hammer as air leaks may result.

No Lubricant

Periodic use of lubricant of any kind on radius rod and air beam rubber bushings is unnecessary. Keep surface of bellows free from oil and grease. When installing bushings in radius rods or air beams, however, a vegetable oil base rubber lubricant can be used on rubber bushing surfaces to help work bushing into position.

MAINTENANCE

Air Tanks

Air tanks must be drained at regular intervals to keep air system as free from moisture as possible.

Air Leakage Test

With the main air system at normal operating pressure (100-105 psi) coat all air suspension system air line connections and bellows mountings with a solution of soap and water. Air leakage will produce soap bubbles. No leakage is permissible.

Leakage at an air line connection can sometimes be stopped by tightening the connection. When an air line connected with a rubber sleeve is used, replace rubber sleeve. If tightening the bellows bead ring bolts does not stop leakage at the bellows mounting, remove, inspect and, if necessary, replace bellows.

Mounting and Bellows Inspection

Make a wrench check for loose radius rod and anchor plate bolt nuts. Inspect all bellows for cracks, abrasions or other damage which might develop into a rupture. Carefully check for and remove tiny stones or other material which may be lodged between bellows and girdle or bead rings. Replace with new bellows if any damage is evident.

Air Filters

Air filter assemblies are used in the height control valve line. Air filters are used at the ports of the valves. These units should be removed, disassembled and cleaned at regular intervals.

Height Control Valves

With the air suspension system at operating pressure of 100-105 psi, the correct normal ride height is determined by measuring the clearance between the axles and frame at points indicated in Figs. 2, 3 and 4. If necessary, adjust the length of the valve arm link to obtain proper clearance. Lengthen the link to increase clearance, and shorten the link to decrease clearance.

At the front axle, check for a 7″ clearance between air bellows support brackets and bellows top plates, Fig. 2. At rear axle, check for a 2¾″ clearance between axle bumpers and bottom of each frame side rail, Figs. 3 and 4. Make sure lock nuts are securely tightened against turnbuckle when adjustments are completed.

Height control valve arm will move $\frac{3}{16}$″ to ¼″ up or down from neutral position without causing any valve action. If the amount of adjustment required falls within these limits, lengthen or shorten the link the required amount. However, the frame will not raise or lower until the load is increased or decreased to actuate the height control valve.

If any one of the height control valves does not function properly with the link correctly adjusted, check for clogged air filters and restricted air lines. If valve does not hold frame at normal ride height with link properly adjusted, clean filters and with no restrictions in the air lines, the height control valve should be removed and overhauled or replaced with a new or rebuilt unit.

Fig. 2 Typical front air suspension installation

FRONT AXLE

Removal, Fig. 2

1. Block rear wheels to prevent vehicle from rolling. Chain axle to frame. Lift frame with jacks to relieve load from suspension and to provide clearance. Securely block frame in raised position.
2. Lower jacks until frame rests on blocks. Jack up front axle and remove chains.
3. Remove wheels. Disconnect air hoses from brake chambers.
4. Release compressed air from supply system by opening drain cock in air tank.
5. Disconnect drag link from steering arm. On models equipped with power steering, disconnect ends of power cylinder from tie rod and axle, leaving cylinder hoses connected.
6. Disconnect height control valve links from brackets on axle. Pull down on valve arm to release compressed air from chambers and bellows.
7. Disconnect upper, lower and lateral radius rods at axle.
8. Remove nuts from bolts attaching

Fig. 3 Typical single rear axle air suspension installation

air bellows lower bead rings to support bracktes on axle.

9. Remove shock absorbers. Lower jacks under axle until bellows bead ring bolts clear bellows bracket and axle clears underside of vehicle. Carefully pull jacks and axle assembly from under vehicle.

Installation

1. If bellows were removed from top plates, install bellows before axle is positioned under vehicle. See that mating surfaces on bellows, bead rings, top plates and support brackets are clean and smooth. Insert bellows bead ring bolts through top plates and attach with nuts and washers. The two long bolts also attach top plate to frame side rail. The stop extension on top plates should be toward front of vehicle. Tighten nuts alternately to draw bead ring evenly against top plates. Tighten bead ring nuts to a torque of 9-14 lb. ft.
2. Clean all dirt, grease or paint out of tapered holes in radius rod brackets. All surfaces contacted by rubber bushings must be clean and dry.
3. Clean surface of bellows support brackets. Support axle with jacks.
4. Carefully move jacks and axle into position under vehicle. Position bellows support brackets directly under bellows. Raise axle at each end until bellows bead ring bolts can be in serted through brackets. Install nuts and washers on bead ring bolts and tighten alternately to draw bead rings evenly against bracket surface. Tighten nuts to 9-14 lb. ft. torque.
5. Connect radius rods and shock absorbers.
6. With axle in normal ride height position, Fig. 2, connect height control valve links to brackets. Adjust links, if necessary, to permit free installation of link bolts without moving height control valve arms out of neutral position.
7. Connect drag link and steering arm.
8. On models equipped with power steering, connect power cylinder to tie rod and axle. Locate tie rod clamp as follows: With wheels turned to extreme right against wheel stops (extreme left on V8 "F" models) and piston rod contracted, position clamp on tie rod. Dimension used to locate clamp on tie rod depends on type of cylinder used. When cylinder has uniform diameter throughout length, position tie rod clamp to provide 5¾" dimension between end of power cylinder head and outer end of piston rod socket. The other type cylinder has a small diameter neck toward the head end of the cylinder. With this cylinder, position clamp to provide 4 11/16" dimension between end of power cylinder head and outer end of piston rod socket. With power cylinder parallel to axle, tighten clamp bolts to 60-65 lb. ft. torque.
9. Connect hoses to brake chambers and install wheels.
10. Raise vehicle and remove blocks from beneath frame. Lower vehicle to floor and remove jacks.
11. Build up pressure in system to normal 100-105 psi. Allow a few minutes for suspension system pressure to build up, then recheck ride height clearance. When installation is completed, make air leak test with soapy water.

Fig. 5 Dimensions of tools for replacing radius rod or air beam bushings

SINGLE REAR AXLE

Removal, Fig. 3

1. Block front wheels to prevent vehicle from rolling. Jack up frame far enough to relieve load on suspension system. Place blocks or solid supports under frame ahead of air beam frame brackets.
2. Release compressed air from air brake system by opening drain cock at air tank. Disconnect air brake hoses at each brake chamber.
3. Disconnect propeller shaft at axle.
4. Remove shock absorbers.
5. Disconnect height control valve links and stabilizer bar links from axle. Pull down on both valve arms to release compressed air from beams and bellows. Disconnect air line at both bellows upper supports.
6. Unfasten rear bellows upper support from frame side rails.
7. Disconnect axle end of radius rod. At top of axle, disconnect both ends of lateral radius rod.
8. Position jack under axle to prevent axle tipping and causing personal injury. Disconnect air beams at frame brackets and at axle.
9. Roll axle assembly from beneath vehicle. Raise frame for additional clearance, if necessary.

Installation

1. Roll axle into position under vehicle.
2. Install air beams and bolt loosely at axle and frame brackets. Clean all dirt, grease or paint from radius rod pins and tapered holes in lateral radius rod brackets. Install radius rod.
3. Raise or lower axle to 2¾" dimension between axle bumpers and frame side rails. Maintain this dimension while tightening anchor

Fig. 4 Typical dual rear axle air suspension installation

plate lock nuts to a torque of 180-220 lb. ft. Then tighten lateral radius rod lock nuts to a torque of 400-450 lb. ft.

4. Install shock absorbers. Connect stabilizer bar link to axle.
5. With axle in normal ride height position, Fig. 3, connect height control valve links to brackets. Adjust links if necessary to permit free installation of link bolts without moving height control valve arms out of neutral position.
6. Insert bellows upper support bolts in holes in frame side rails. With each support evenly seated against underside of frame side rail, install washers and nuts and tighten securely.
7. Connect propeller shaft.
8. Connect air line to each bellows upper support. Connect air brake hoses at each brake chamber.
9. Raise vehicle and remove blocks from beneath frame. Lower vehicle to floor and remove jacks.
10. Build up air pressure to the normal 100-105 psi operating pressure. Allow a few minutes for pressure to build up, then recheck riding height clearance.
11. Check system for air leaks with soapy water.

Fig. 6 Air filter assembly

DUAL REAR AXLES

The following procedure covers removal and installation of the dual rear axles as a complete assembly. Either the front or rear unit can be removed separately by making the necessary disconnections.

Removal, Fig. 4

1. Block front wheels to prevent vehicle from rolling. Use chain fall to lift frame and relieve load on suspension system. Do not lift frame high enough to damage bellows.
2. Release compressed air from air brake system by opening drain cock at air tank.
3. Disconnect propeller shaft from rear axle front unit.
4. Disconnect air lines from brake chambers and from differential lock.
5. Disconnect height control valve links. Pull down on both valve arms to release compressed air from beams and bellows.
6. Disconnect air lines at both front bellows upper supports.
7. Remove shock absorbers.
8. Disconnect stabilizer bar link from axle.
9. Remove two nuts attaching each bellows upper support to frame.
10. Remove two bolts from axle end of lateral radius rod at each axle. Disconnect each lateral radius rod from frame bracket.
11. Remove radius rod between rear axle front unit and frame crossmember.
12. Remove two radius rods between rear axle front unit and radius rod frame brackets.
13. Raise frame to provide clearance for removing dual rear axle assembly. Block frame side rails securely at rear of radius rod frame brackets.
14. Roll axle unit from under vehicle.
15. If necessary to separate axles, support each axle to keep axles in an upright position. Disconnect air beams and radius rod.

Fig. 7 Pressure regulating valve

Installation

1. If removed, install four air bellows and upper brackets on air beams. Align front and rear axle and attach air beams and radius rod. *Bolt unit together loosely.*
2. Roll dual axle assembly into place under vehicle frame. Remove blocks from under frame and lower frame to normal position.
3. Install upper radius rod between rear axle front unit and frame cross-member.
4. Install two radius rods between axle and radius rod frame brackets.
5. Clean all dirt, grease and paint from rod pins and tapered holes in lateral radius rod frame brackets. Install radius rod at each axle.
6. Raise or lower axle to 2¾″ dimension between axle bumpers and frame side rails, Fig. 4. Maintain this dimension while tightening anchor plate lock nuts to 180-200 lb. ft. torque. Tighten lateral radius rod lock nuts at frame bracket only to 400-450 lb. ft. Tighten lateral radius rod axle bracket bolt nuts securely. Install lock wires in heads of all cap screws which thread into welded nuts or tapped holes in axle housing.
7. Insert bellows upper support bolts in holes in frame side rails. With each support evenly seated against underside of frame side rail, install two lock washers and nuts and tighten securely.
8. While holding the 2¾″ dimension between frame and axle bumpers, connect height control valve links to brackets. Adjust links if necessary to permit free installation of link bolts without moving height control valve arms out of neutral position.
9. Connect propeller shaft, install shock absorbers and connect stabilizer bar link.
10. Connect air brake lines at each brake chamber. Connect air line to each bellows front upper support. Connect differential lock air line at rear axle front unit.
11. Build up air pressure in system to normal operating pressure (100-105 psi). Allow a few minutes for pressure to build-up, then recheck ride height clearance.
12. Check system for air leaks with soapy water.

RADIUS RODS

To remove radius rods, raise frame just far enough to remove load from suspension system. Block frame securely. When difficulty is encountered in removing tapered pin, use a suitable wedge tool.

When installing radius rods, clean all dirt, grease or paint from rod pins and tapered holes in mounting brackets. Before final tightening of radius rod and air beam anchor plate bolts and nuts, obtain correct clearance dimensions as shown in Figs. 2, 3 and 4. If connections are tightened without first obtaining this clearance, a torsional preload will be imposed on rubber bushings when the frame assumes normal height relative to axles.

When it becomes necessary to replace radius rod bushings, a press and tools made to the dimensions shown in Fig. 5 should be used.

AIR BELLOWS

Removal

1. Support frame with wood blocks.
2. Place 2¾″ blocks between rear axle bumpers and frame side rails.
3. Place 7″ blocks between front axle bellows supports and top plates.
4. If compressed air has been exhausted due to leakage, frame should be raised and blocked to facilitate replacing bellows.
5. If system is pressurized, disconnect height control valve link and pull valve arm down to exhaust compressed air from air chamber and bellows. *Do not disturb height control valve adjustment.*
6. Separate bead rings from support bracket and top late at front axle or from upper and lower support flanges at rear axle.

Installation

Examine bellows inside and out for evidence of cracks, punctures, deterioration or chafing. Replace with new bellows if any damage is evident. Bead rings and girdle ring can be removed from defective bellows and installed on new bellows. Clamping surfaces of bead rings must be clean and smooth. When installing bead rings on bellows, holes in upper and lower rings must be aligned so that no twist will be imposed on bellows during installation. *Undercoating material, if used, should be kept off surface of bellows, as this material could eventually cause air leaks.*

After bellows is installed, build up pressure in system to normal operating pressure. Remove blocks at axles. Check for leakage at upper and lower bellows mounting with soapy water. Any leakage evidenced by the appearance of bubbles should be corrected.

AIR FILTERS

Air filters, Fig. 6, are used at inlet and outlet ports of front and rear height

Fig. 8 Schematic diagram of height control valve

control valves. Any foreign matter carried by air being exhausted from air chamber is trapped before air enters height control valve. Air filters should be removed and serviced at regular intervals. Clogged air strainers will retard flow of compressed air into and out of suspension system.

Removal

1. Securely support frame with wood blocks. Place 2¾″ blocks between rear axle bumpers and frame side rails. Place 7″ blocks between front axle bellows supports and top plates.
2. Exhaust compressed air from air tank by opening drain cock.
3. Disconnect height control valve link at valve and pull down arm to exhaust compressed air from bellows and air chamber. Do not disturb link adjustment.
4. Disconnect air lines from elbows or connectors at filter assemblies. Unscrew air filters from control valve bodies or from elbow in control valve body. Remove connector bodies or elbows from air filters.

Assemble and Install

After cleaning all parts, blow dry with compressed air. Blow air through bronze filter from inside of cone. Discard old grommet and use a new one when assembling. Coat new grommet with Lubriplate or equivalent. Use Permatex No. 3 sparingly on all male threads, *but not on the first two threads*. After installation is completed, build up pressure in the system and check for air leaks.

Fig. 9 Exploded view of height control valve

PRESSURE REGULATING VALVES

This valve, Fig. 7, is mounted on a bracket at the air tank. One purpose of this valve is to prevent air pressure from entering the air suspension system until pressure in the air brake system reaches 65 psi. This provides a rapid build-up of air pressure for operation of the brakes. When brake system air pressure exceeds 65 psi, the pressure regulating valve opens and allows pressure to build up in the air suspension system.

A second purpose of the pressure regulating valve is to prevent loss of brake system air pressure below 65 psi due to leakage in air lines or in the air suspension system.

Operating Test

1. Exhaust compressed air from air system by opening drain cock at air tank. Close drain cock when tank is empty.
2. Connect a test air pressure gauge in brake system, preferably in the line leading from the air tank to the pressure regulating valve.
3. Disconnect one of the air lines from the tee fitting at the bottom of the pressure regulating valve.
4. Build up air pressure in the system and note the pressure on the test gauge at the same time the valve opens and discharges air through the open line.
5. Adjust valve if pressure varies 5 psi from the original setting (65 psi).

Leakage Test

With air line still disconnected from tee at bottom of valve, build up air pressure to a point just below valve setting (65 psi). Coat opening in tee with soap suds to check for leakage. Also apply soap suds to vent opening in valve cover.

No leakage is permissible at vent opening in valve cover. Leakage at this point indicates a ruptured diaphragm. Replace diaphragm with new part.

Leakage amounting to a 3-inch bubble in 3 seconds at outlet port is permissible. Excessive leakage is an indication of dirty or worn valve or valve seat.

Adjusting Pressure

The adjusting screw, Fig. 7, controls the pressure at which the valve is unseated. The setting may be increased or decreasd by turning the screw after loosening the lock nut.

HEIGHT CONTROL VALVE

Before disconnecting any height control valve air lines, securely support the frame. Place blocks between the bellows supports and top plates at the front axle and between the axle bumpers and frame at the rear axle. Exhaust compressed air from the air supply system by opening the drain cock at the air tank. After the above precautions have been taken, remove any valve as follows:

Removal

Disconnect the valve link from the valve arm. Pull the arm downward to release compressed air from the bellows and air chamber (front) or air beam (rear). Disconnect air lines at valve. Then unfasten and remove valve. Remove air filters and elbows from valve for installation on the replacement unit.

Installation

Before installing a height control valve, see that all air line fittings are

clean and undamaged. Replace connector rubber sleeves if damaged. Absolute cleanliness is essential when installing height control valves. Dirt and thread sealing compound must be kept out of valves. Even minute particles of foreign matter may become lodged on check valve or control valves seats and seriously affect operation of the suspension system.

When installing a valve, apply Permatex No. 3 on the male threads of fittings, *but not on the first two threads.* After the valve is installed, build up pressure in the system and test for leaks with soapy water.

Valve Service

Height control valves, Figs. 8 and 9, meter air into and out of the air suspension system. These valves must be precision built and accurately calibrated. Parts must be carefully handled and assembled and valves must be accurately adjusted to insure proper operation. Special tools must be used. Improper tools may break off chips that could lodge between valves and seats. Chips, dirt or other foreign matter are most generally the cause of improper valve operation. It is strongly recommended, therefore, that faulty valves be exchanged for new or rebuilt units.

Front End & Steering Gear Section

TORSION BAR SUSPENSION

Series 1000 Thru 3000

As shown in Fig. 1, the front end of each torsion bar is supported by a steel tube in the lower control arm. The hexagon end of the torsion bar engages a hexagon section at the center of the tube. The rear end of the torsion bar is supported in an adjustable anchor connected to a special crossmember. Shims used between control arm shaft spacers and frame bracket provide for adjustment of caster and camber.

Series 3500 Thru 5000

As shown in Fig. 2, the front end of each torsion bar is supported in the upper control arm. The hexagon end of the torsion bar engages a hexagon section at the center of the control arm. The rear end of each torsion bar is supported in a fixed bracket attached to the frame side rail. Shims between brackets and frame provide for camber adjustment. Notches in the lower control arm shaft and in the plate welded to the crossmember provide adjustment for caster.

Fig. 1 Torsion bar suspension. Series 1000 thru 3000

VEHICLE CURB HEIGHT, ADJUST

Vehicle curb height should be checked and corrected if necessary to obtain the dimensions shown in Fig. 3 before making caster and camber adjustments. This measurement is taken from the bottom edge of the crossmember to top outer flange of lower bumper bracket at centerline of spindle.

On Series 1000 thru 3000, curb height adjustment may be made by adjusting the torsion bar anchor bolt.

On Series 3500 thru 5000, no adjustment is provided, as specified curb height will be obtained by installation of the proper torsion bar.

CASTER & CAMBER, ADJUST

Series 1000 Thru 3000

Caster and camber adjustments are made by means of shims between upper control arm spacer and the bracket attached to the frame. Shims may be changed at either front or rear bolt to change caster or at both points equally to change camber.

To enable more accurate settings, adjustments are based on a .0299″ shim. It is advisable to use .0598″ or .1196″ of shimming where possible to reduce the number of shims that have to be handled. The shim pack should not exceed ⅝″ (twenty-one .0299″ shims).

The total difference in shims between front and rear bolts should not exceed $\frac{21}{64}$″ (eleven .0299″ shims).

For caster changes, one .0299″ shim added to rear bolt changes caster a minus 24′ and camber a minus 1′. One .0299″ shim removed from rear bolt changes caster a plus 24′ and camber a minus 2′.

For camber changes, one .0299″ shim added or removed from both bolts changes camber plus or minus 10′ 38″. To adjust, proceed as follows:

1. Check and adjust curb height of vehicle.
2. Determine present caster and camber setting of one wheel.
3. Add or remove shims as suggested above.
4. After shims have been changed, check result.
5. Repeat on opposite wheel.

Series 3500 Thru 5000

Caster Adjustment

1. Check caster to determine amount of shim changes required.
2. Mark location of control arm shaft with reference to notched attaching plate, Fig. 2 (inset).
3. Loosen four shaft-to-crossmember bolts to free shaft from notches in attaching plates.
4. Move shaft rearward to decrease caster or forward to increase caster. Moving shaft one notch changes caster approximately ½°.
5. Tighten bolts and recheck adjustment.

Camber Adjustment

1. Check camber to determine amount of change required.
2. Remove two upper bolts and nuts

Fig. 2 Torsion bar suspension. Series 3500 thru 5000

attaching control arm brackets to frame and loosen two lower nuts.
3. From inside frame, remove and discard (if present) two countersunk clutch head screws at each bracket.
4. Lift vehicle at front crossmember until control arm bracket can be pried away from support.
5. Insert or remove shim at both bolts equally as required. The addition of a shim at both bolts increases camber about ½°.

TOE-IN, ADJUST

All Series

Toe-in is adjusted by loosening the clamp bolts at each end of steering outer links and turning each link to decrease or increase its length as necessary to obtain correct toe-in. Tighten clamp bolts securely after adjustment is made.

TORSION BARS, REPLACE

Torsion bars for different load ratings and for various truck models are identified by colored bands and by overall length. The right-hand bars have one color band and left-hand bars have two color bands. Color bands are located near rear end of bars and also serve to identify front and rear ends. It is imperative that both torsion bars on a vehicle have the same colored markings. Exercise caution in handling torsion bars to prevent nicks or scratches, since stress concentrations and corrosion can lead to failure of the bar in operation.

Removal, 1000 Thru 3000

1. Referring to Fig. 1, remove upper control arm bumper.
2. Remove shock absorber lower anchor stud.
3. Raise vehicle with wheel suspended and support frame with upper control arm resting on crossmember.
4. Unscrew nut on adjusting bolt to unwind torsion bar, then remove torsion bar arm from rear end of torsion bar.
5. Pull torsion bar rearward out of lower control arm tube and remove from vehicle.

Installation, 1000 Thru 3000

1. Front end of frame must be blocked up with upper control arm resting on crossmember.
2. Install front end of torsion bar into rear side of torsion bar tube in lower control arm. Slide bar forward until it stops against dimple in tube. This locates fore and aft position of bar.
3. Place spacer on torsion bar adjusting bolt, insert bolt through torsion bar anchor crossmember and start nut on bolt. Thread nut on bolt until bolt engages about half the threads in nut.
4. Place torsion bar arm on rear end of bar with hook on inner end of arm engaging adjusting bolt; spacer must be below arm. Position arm on torsion bar so rear face of arm is flush with rear end of bar within plus or minus $\frac{3}{32}$"; this is to prevent failure of bar due to stress developing if front corners of hex ride on edges of hex on bar. Partially tighten nut on adjusting bolt.
5. Remove blocking from under frame and lower vehicle to floor.
6. Secure shock absorber lower anchor stud.
7. Install upper control arm bumper.
8. Tighten nut on torsion bar adjusting bolt on each side until vehicle assumes nominal curb height shown in Fig. 3.
9. Measure distance from outer ends of front bumper to floor. Distance at both ends must be equal within ¼".
10. Check and if necessary adjust wheel alignment.

Removal, 3500 Thru 5000

1. Referring to Fig. 2, remove upper control arm bumper.
2. Remove shock absorber lower anchor pin.
3. Remove outer link ball stud from steering knuckle arm.
4. Jack up vehicle with wheels suspended until control arm rests on crossmember to remove load from torsion bar. Place jack under frame or crossmember and block vehicle securely after raising.
5. Using a long, thin punch, drive torsion bar lock pin frame bracket and discard pin, using a new one upon reassembly.
6. On long wheelbase models having sufficient distance between torsion bar frame bracket and rear spring frame bracket, move torsion bar rearward and remove through frame bracket.
7. On short wheelbase vehicles, move torsion bar rearward until front end is clear of upper control arm. Place blocking under lower control arm and tire, and have an assistant hold wheel to prevent it from tipping out-

ward when upper control arm is disconnected from frame. Unfasten upper control arm brackets from frame, noting number of shims under each bracket so the same shims can be installed on reassembly. Lift upper control arm and brackets to permit moving torsion bar forward.

8. Move bar forward until rear end is clear of frame bracket, then manipulate bar as necessary to remove vehicle.

Installation, 3500 Thru 5000

1. On long wheelbase vehicles, insert front end of torsion bar through frame bracket from rear side, then move bar forward. Guide front end of bar through upper control arm as rear end engages frame bracket. Lock pin notch in hex portion of rear end of bar must index with lock pin hole in frame bracket. Drive new pin into hole until flush with top of bracket.
2. On short wheelbase models, lift upper control arm and bracket assembly to permit inserting rear end of torsion bar through frame bracket. Move bar rearward until front end will clear upper control arm rear bracket. Attach upper control arm brackets to frame, being sure to use the same shims that were removed under each bracket. Tighten nuts on control arm bracket bolts. Remove blocking from under lower control arm and tire. Align lock pin notch in bar with hole in frame bracket, then move bar forward, guiding front end into upper control arm. Drive new lock pin into hole until flush with top of bracket.
3. Remove blocking and lower vehicle to floor.
4. Install upper control arm bumper and shock absorber lower anchor pin.
5. Connect steering outer link ball stud.
6. Check wheel alignment.

FRONT SUSPENSION SERVICE 1000 THRU 3000

Lower Ball Joint

1. To check the lower ball joint for wear, support weight of vehicle on tires.
2. Using outside micrometer or caliper, measure distance from bottom of lube fitting at bottom of ball joint to top of ball stud and record the dimension. Repeat at lower ball joint at opposite side of vehicle.
   Support vehicle weight at outer end of each lower control arm so that wheels are clear of floor; then repeat measurement as outlined above.
3. If the difference in loaded and unloaded dimensions on either side is greater than $\frac{3}{32}$", the joint is excessively worn and both lower ball joints should be replaced.
4. If the above measurements do not indicate any reason for ball joint replacement, test the torque tightness of the stud nut at each side of the vehicle as follows:
5. Clean dirt from area and check for looseness of stud in steering knuckle.
6. If looseness is not evident, remove cotter pin and mark stud and nut with a punch to identify their relative positions.
7. Loosen stud nut, then retighten to original position and observe torque reading. If less than 45 ft lbs torque is required to return nut to its original position, stud was probably loose in steering knuckle and replacement of ball joint is recommended.
8. If replacement of ball joint is required, remove control arm and replace joint, tightening stud nut to a torque of 175-200 ft lbs.

Fig. 3 Measuring vehicle curb height

Fig. 4 Position of control arm shafts. 1960 Series 1000 thru 3000

Upper Ball Joint

1. The ball joint can be checked for wear by checking the torque re-

Fig. 5 Saginaw recirculating ball and nut steering gear

Fig. 6 Layout of a Saginaw ball and nut steering gear

quired to rotate the ball stud as follows:

2. Remove upper control arm bumper.
3. Remove shock absorber lower anchor stud.
4. Raise vehicle with wheel suspended and support frame with upper control arm resting on top of crossmember.
5. Loosen nut on adjusting bolt to unwind torsion bar.
6. Remove cotter pin and loosen stud in steering knuckle by striking sides of knuckle at flats adjacent to stud. Then remove nut, separate upper stud from knuckle and remove rubber seal (wheel must be supported while upper control arm is disconnected from top of knuckle).
7. Install nut on stud and measure torque required to turn stud. Torque should be at least 2 ft lbs. If excessive wear is indicated at this joint, both upper and lower joints should be replaced. If a tight joint is suspected, maximum allowable torque to turn stud, with joint well lubricated, should be 15 ft lbs.
8. If replacement is not necessary, install and attach parts and torque stud nut to 100-135 ft lbs. *It will be necessary to adjust tension on torsion bar as outlined under Torsion Bar, Replace.*

Steering Knuckle

Removal

1. Jack up vehicle and support frame.
2. Remove torsion bar.
3. Remove wheel, hub and drum.
4. Remove backing plate and brake shoes.
5. Remove nut from upper ball stud.
6. Remove nut from lower ball stud.
7. Drive lower ball stud out of steering knuckle and remove knuckle from upper ball stud.

Installation

1. Install new seal over upper and lower ball studs.
2. Position steering knuckle over upper ball stud and install nut.
3. Lift lower control arm, guiding ball stud through lower end of knuckle and install nut on stud.
4. Tighten upper stud nut to a torque of 175-200 ft lbs and lower stud nut to 100-135 ft lbs and install cotter pins.
5. Install remaining parts removed.

Upper Control Arm

Removal

1. Remove torsion bar.
2. Remove control arm mounting nuts.
3. Lift control arm and shaft off mounting bolts. Tag and identify each shim pack so they can be installed in original position.
4. Unscrew bushing from control arm and shaft. Remove shaft and slide off seals.

Installation

1. Assemble bushings and shafts as indicated in Fig. 4.
2. Turn bushings in until inner surface of hex bottoms on outer edge of control arm. Tighten bushings to a torque of 105-120 ft lbs on Series 1000 and 1500. On Series 2500 and 3000 torque is 125-140 ft. lbs.
3. Torque shaft mounting bolts to 60-80 ft lbs on Series 1000, 90-120 on 1500, and 130-170 on 2500 and 3000.
4. Install remaining parts removed.

Lower Control Arm

Removal

1. Remove torsion bar.
2. Remove control arm and shaft from crossmember.
3. Unscrew bushings from shaft and arm.
4. Remove shaft and slide off seals.

Installation

1. Install new seal over each end of control arm.
2. Install shaft in arm. Lubricate inner threads of bushings and thread bushings onto shaft and into control arm. Turn shaft until it is centered in control arm as indicated in Fig. 4. Then turn bushings in until inner surface of hex bottoms on outer edge of arm.
3. Tighten bushings to a torque of 125-140 on Series 1000 and 1500. On 2500 and 3000 torque is 145-160 ft lbs. Check shaft for free rotation.
4. Install control arm and shaft and tighten mounting bolts to a torque of 90-115 ft lbs on 1000 and 1500 and 145-185 on 2500 and 3000.
5. Install remaining parts removed.

FRONT SUSPENSION SERVICE 3500 THRU 5000

Upper Ball Joint

Check the condition of upper ball joints in the same manner outlined for *lower* ball joint on 1000-3000 models.

Lower Ball Joint

Check condition of lower ball joint in the same manner outlined for the *upper* ball joint on 1000-3000 models. However, the torque required to turn the stud should be at least 5 ft lbs. And if a tight joint is suspected, maximum allowable torque, with joint well lubricated, should be 20 ft lbs.

Steering Knuckle

1. Remove upper control arm bumper plate and bumper.
2. Remove shock absorber lower anchor pin.
3. Remove tie rod ball stud from steering knuckle.
4. Raise vehicle with wheels suspended until upper control arm rests on top of crossmember to remove load from torsion bar. Place jack under frame or crossmember and block vehicle securely after raising.
5. Remove wheel, hub and drum.
6. Remove brake shoes. Disconnect flexible brake lines at brake backing plate or at brake chamber (air brakes). If equipped with air brakes, remove brake chamber and slack adjuster. Remove backing plate from knuckle.
7. Remove nuts from upper and lower ball studs.
8. Drive lower ball stud out of knuckle and remove knuckle from upper ball stud.
9. Installation is accomplished in the reverse order of removal.

Lower Control Arm

1. Perform Steps 1 to 4 under *Steering Knuckle.*
2. Mark lower control arm snaft and notched plate welded to crossmember so shaft can be installed exactly in the same position.
3. Unfasten and remove lower control arm and shaft from crossmember.
4. Remove lower control arm bumper plate and bumper.
5. Remove lower ball stud and bracket and spacing sleeves from control arm.
6. Unscrew control arms from shaft and remove O-ring seal from groove in inner side of each arm.
7. Installation is accomplished in the reverse order of removal. However, thread the control arms on the shaft until the threads bottom, and back off each arm a minimum of ⅛ turn; then back off an additional amount as necessary for both arms to point in the same direction.

Upper Control Arm

1. Perform Steps 1 to 4 under *Steering Knuckle.*
2. Drive torsion bar lock pin out of frame bracket, using a long, thin punch.
3. Move torsion bar rearward until front end is clear of upper control arm rear bracket.
4. Remove upper control arm and brackets, noting the number of shims used under each bracket so the same shims can be installed at assembly.
5. Slide brackets off control arm.
6. Remove O-ring seals from grooves in outer ends of control arm and inside brackets, and remove thrust washers from bores of brackets.
7. Installation is accomplished in reverse order of removal.

SAGINAW BALL & NUT STEERING GEAR

1952-63

The steering gear, Figs. 5 and 6, is the recirculating ball type. The principal working arrangement consists of a "ball nut" connected to the steering worm and in mesh with the sector gear. Precision finished helical grooves inside the ball nut match helical grooves in the worm, and it is in these grooves that ball bearings roll around as the steering wheel is turned.

There are two complete ball circuits within the ball nut. To keep the balls from running out of the end of either circuit, the nut is equipped with two tubular ball guides, each of which deflects the balls away from their helical path at one end of their travel, guides them diagonally across the back of the nut and returns them to their helical path between the ball nut and the worm at the other end of their travel.

The balls constitute a thread between the worm and ball nut so that when the worm is turned, the nut moves along the worm as with an ordinary screw thread.

Fig. 7 Checking load on steering gear with spring scale at steering wheel rim

Fig. 8 Filling ball circuits in nut

Fig. 9 Filling ball guides

Fig. 10 Checking lash adjuster end clearance

STEERING GEAR ADJUSTMENTS

1952-59

There are only two adjustments to be made on this gear and the following procedure must be made step-by-step in the order given.

1. Disconnect drag link from pitman arm.
2. Loosen the sector shaft lock nut and turn the adjusting screw a few turns counter-clockwise, Fig. 6. This removes from the worm bearings the load imposed by close meshing of rack and sector teeth. Turn steering gear gently in one direction until stopped by gear, then turn it back one turn.
3. With a spring scale, Fig. 7, measure the pull at the rim of the wheel which is required to keep the wheel in motion. This should be between 1 and 1½ lbs. up to model 470 and 1½ to 2 lbs. on larger models. If the pull necessary to move the wheel does not lie between these limits, adjustment of worm bearings is necessary.
4. To adjust worm bearings. loosen the worm shaft lock nut and turn the worm bearing thrust screw until there is no perceptible end play in worm. Check pull at wheel rim, readjusting if necessary to obtain proper pull. Tighten lock nut and recheck pull as it must be within proper limits after lock nut is tightened.
5. After proper adjustment of worm is obtained and all mounting bolts securely tightened, adjust cross shaft lash adjuster as follows:
6. First turn steering wheel gently from one stop to the other, carefully counting total number of turns. Then turn wheel back half way to center position. Mark wheel at top or bottom center with a piece of tape.
7. Turn lash adjuster clockwise to take out all lash in gear teeth and tighten lock nut.
8. Check pull at wheel rim with spring scale as before, taking highest reading on scale as wheel is turned through center position. This should be between 2 and 2½ lbs. on models up to 470 and 2½ to 3 lbs. on larger models.
9. Readjust if necessary to obtain proper pull. Tighten lock nut and recheck pull as it must be within proper limits after lock nut is tightened.
10. Connect drag link to pitman arm.

1960-63 With One Piece Steering Shaft

To adjust worm bearings, loosen lock nut and turn worm bearing adjuster screw clockwise until all lash is removed. Using spring scale hooked to steering wheel rim, check amount of pull required to keep wheel moving. Reading on scale should be 1½ to 2 lbs. Turn adjuster screw as necessary to obtain correct adjustment.

To adjust pitman shaft lash, place steering wheel in its exact straight ahead position. Turn lash adjuster screw

clockwise to remove all lash. When all lash has been removed tighten lash adjuster lock nut to 25-35 ft lbs. Greatest pull when wheel is pulled through center position is 2¾ to 3¼ lbs.

1960-63 With Two Piece Steering Shaft

Proper adjustment of worm bearings is obtained by adding or removing shims between steering gear housing and end or top cover. Drain lube from gear housing. Remove top or end cover and shim pack. Discard one thin shim and reinstall cover with remaining shims. Check steering wheel rim pull with spring scale attached to rim. Reading on scale should be 1½ to 2 lbs. Add or remove shims as required to obtain proper adjustment.

Pitman shaft adjustment is accomplished in the same manner outlined above for P1500 models.

STEERING GEAR, REPLACE

1952-59 (Except C.O.E.)

1. Disconnect horn wire and remove wire retainer from steering mast jacket.
2. Remove horn button and steering wheel.
3. Remove seat cushion except on Forward Control models.
4. Unfasten mast jacket from instrument panel.
5. On ½ and ¾ ton, disconnect gear shift upper control shaft support from mast jacket. Separate upper control shaft from lower shaft by removing lower bolt from shaft clamp.
6. Unfasten and slide toe board grommet and seal up on mast jacket and remove toe board plate.
7. On Forward Control models, hoist front end of vehicle and remove mast jacket opening cover located underneath vehicle.
8. On ½ and ¾ ton, unfasten gearshift control housing from mast jacket.
9. Unfasten gear housing from frame.
10. On Forward Control models, gear can now be moved forward, down and out of vehicle.
11. On all other models, unfasten and move left fender skirt out of the way.
12. Slide steering gear slightly upward toward toe board, then rotate until attaching flange is up. Raise slightly and lift gear out over fender.
13. Reverse the foregoing procedure to install the gear.

1952-59 C.O.E.

1. Remove steering wheel and disconnect dash mounting bracket.
2. Remove left hand floor pan and steering column grommet.
3. Disconnect horn wire.
4. Remove signal switch bowl.
5. Remove fender skirt.
6. Remove pitman arm.
7. Unfasten gear from frame.
8. Move gear back to clear radiator grill. Then drop gear down through fender skirt opening, pulling steering column through opening in floor.
9. Reverse above procedure to install gear.

1960-63 Models With One Piece Steering Shaft

1. Remove steering wheel with puller.
2. Remove spring and insulator from top of steering shaft.
3. Disconnect all control linkage, horn parts and mounting brackets attached to steering column.
4. Disconnect steering linkage from pitman arm; then remove pitman arm with puller. On some models it may be impossible to remove the pitman arm until steering gear is removed from vehicle.
5. Unfasten steering gear housing from frame and remove.
6. Reverse removal procedure to install.

1960-63 With Two Piece Steering Shaft

1. If necessary, loosen steering column mountings.
2. Mark steering gear shaft and clamp yoke on steering column so they can be assembled in the same position when reinstalled.
3. Remove steering column shaft from steering gear shaft.
4. Disconnect steering linkage from pitman arm.
5. If possible remove pitman arm with puller. If this cannot be done with the gear in the vehicle, do it when the gear is removed.
6. Unfasten and remove steering gear from frame and out of vehicle.
7. Reverse removal procedure to install gear.

STEERING GEAR SERVICE

Disassemble

As with any ball or roller bearing unit, the steering gear parts must be kept free of dirt. Clean paper or cloth should be spread on the bench before starting to repair the steering gear.

1. Back off lash adjuster a few turns.
2. Back off worm bearing thrust screw a few turns.
3. Place a pan under assembly to catch lubricant, unfasten side cover and pull it with sector shaft from housing.
4. On ½, ¾, 1 and 1½ ton conventional models, slide mast jacket and upper housing cover up and off worm shaft. Lift worm shaft and nut from housing. Remove lower worm bearing lock nut adjuster and bearing.
5. On Forward Control and larger models, remove housing end cover and lower worm bearing. Draw worm shaft and nut from housing. Lay assembly flat on bench so that ball nut will not thread down to either end.
6. Remove lock nut from lash adjuster and unscrew lash adjuster from side cover. Slide lash adjuster out of slot in end of sector shaft.

Ball Nut, Disassemble

Unless there is a definite indication of binding or tightness when the ball nut is rotated on the worm, the ball nut need not be disassembled.

1. Remove screw (or screws) and clamp retaining ball guides in nut. Draw guides out of nut.
2. Turn nut upside down and rotate worm shaft back and forth until all balls have dropped out of nut into a clean pan. With all balls removed, pull nut endwise off shaft.

Inspection

With all parts cleaned and dry, use a magnifying glass to inspect roller bearings, cones, worm and nut grooves, and the surface of all balls for indentations. Also check for any signs of chipping or breakdown of surfaces.

Inspect sector shaft for wear and check fit of shaft in housing bushing.

Inspect fit of pilot on end of sector shaft in its bushing in side cover. If this bushing is worn, a new side cover and bushing assembly should be installed as it is impractical to replace this bushing in the field.

Check ball guides for any damage at the ends where they deflect or pick the balls from their helical path. Any damaged guides should be replaced.

Ball Nut, Assemble

1. Place worm shaft flat on bench and slip nut over worm. Align grooves in worm and nut by sighting through ball guide holes.
2. Evenly divide the number of balls and place them in separate pans, Fig. 8.
3. Drop the balls from one pan into one of the guide holes while turning the worm gradually away from that hole. Continue until the ball circuit is full. In cases where the balls are stopped by the end of the worm, hold down those balls already dropped into the nut with the blunt end of a clean rod or punch, Fig. 8, and turn the worm in the reverse direction a few turns. It may be necessary to work the worm back and forth, holding the balls down first in one hole then the other to close up the spaces between the balls and fill the circuit completely and solidly.
4. Lay one half of the ball guide on the bench and fill the guide with balls, Fig. 9. Close this half of guide with the other half. Hold the two halves together and plug each open end with vaseline so balls will not drop out while installing guide.
5. Push guide in holes of nut. If the guide does not push all the way down easily, tap it lightly into place.
6. Fill second ball guide in same manner.
7. Assemble ball guide clamp to nut, being sure to use lock washers under clamp screws and tighten screws.
8. Check assembly by rotating nut on worm to see that it moves freely. If there is any "stickiness" in the motion of the nut, some slight damage to the ends of the ball guides may have been overlooked.

Steering Gear, Assemble

The threads of the adjuster cap, side cover bolts and lash adjuster should be coated with a suitable sealer such as

Permatex No. 2. The compound should not be applied to female threads, and extreme care should be exercised in applying this compound to the bearing adjuster cap, as the compound must be kept away from the bearing race.

1. On light duty conventional models, place worm shaft and nut into housing and place upper roller bearing over worm shaft. Place new end cover gasket over end of worm shaft, making sure horn wire is through opening in mast jacket and slide housing end cover with mast jacket over worm shaft and assemble to housing. Install lower roller bearing, worm bearing adjuster and lock nut in lower end of housing.
2. On Forward Control, medium and heavy duty models, place upper worm bearing over worm shaft. Then, after making sure horn wire is through its opening in housing, place worm shaft and nut in housing. Back worm bearing adjuster out of housing end cover a few turns. Install lower roller bearing and assemble lower end cover to housing, using a new gasket.
3. On all models, assemble lash adjuster with shim in slot in end of sector shaft. Check end clearance which should not be greater than .002″, Fig. 10. Various thickness shims are available to obtain this clearance.
4. Start sector shaft pilot into bushing in side cover. Then, using screw driver through hole in cover turn lash adjuster to the left (counterclockwise) to pull pilot into its bushing as far as it will go.
5. Rotate worm shaft by hand until ball nut is in center of its travel, so that the center tooth of sector enters center tooth space of nut.
6. With new gasket in place, push side cover with sector shaft in place. After making sure there is some lash between rack and sector teeth, tighten side cover bolts.

ENGINE DESCRIPTION

The D-301 engine is a six-cylinder in line, valve-in head, four cycle diesel. It is of conventional International design except that it uses a direct fuel injection system. The fuel system consists of the fuel lines, fuel filters, and injection pump, injection nozzles and lines, Figs. 1 to 4.

Fuel Injection Pump

The Roosa fuel injection pump, Fig. 5, is a single cylinder, opposed plunger, inlet metering, distributor type pump. The main components are the drive shaft, distributing rotor, transfer pump, pumping plungers, internal cam ring, hydraulic head, end plate, governor, solenoid shut-off, and speed advance mechanism.

The rotating members revolve around a common axis and are the drive shaft, distributor rotor (containing the plungers and governor) and the transfer pump.

The driving member is the drive shaft that engages the distributor rotor by means of a tang-in-slot that revolves the rotor in the hydraulic head. The drive end of the rotor has a diametric bore containing two opposed plungers. The opposite end of the rotor serves as the transfer pump rotor.

The speed advance mechanism provides for fuel injection at the most desirable time for various engine speeds.

Injection Pump Operation

Governor—The variable speed governor is mounted on the drive end of the distributor rotor. The action of the weights in their retainer is transmitted through a sleeve to the governor arm and through a linkage to the metering valve. The governed engine speed is the speed at which the force of the governor weights and the force of the governor spring is balanced on the governor arm. The pressure of the spring on the governor arm can be varied, thus providing variable governed engine speed. The light

Fig. 1 Right front view of D-301 diesel engine

Fig. 2 Left front view of D-301 diesel engine

Fig. 3 Cross sectional view of D-301 diesel engine

idle spring provides sensitive governor action at low engine speeds. A governor linkage hook that is connected to the metering valve is actuated by the governor arm.

Rotor—The drive end of the rotor has a bore containing two plungers. The plungers are moved toward each other simultaneously through shoes and rollers actuated by a six-lobe internal cam ring. The shoe, which provides a large bearing surface for the roller, is carried in guide slots in the rotor.

The rotor shaft rotates with a very close fit in the hydraulic head. A passage through the center of the rotor shaft connects the pumping cylinder with one charging port and one discharge port. The hydraulic head in which the rotor shaft turns has six charging ports and six discharge ports.

Transfer Pump—A positive displacement, vane type fuel transfer pump is at the end of the rotor shaft. Fuel pressure developed by the fuel transfer pump is controlled by a pressure regulator valve in the pump end plate. A passage at the top of the transfer pump facilitates removal of air introduced in the system.

Fig. 4 Major components of diesel fuel system

This passage connects with the pump housing through the fuel return line to the supply tank.

Fuel Flow—Fuel is drawn from the final filter into the pump through the inlet strainer by the fuel transfer pump. The transfer pump capacity exceeds the fuel required for injection; therefore, a large percentage of fuel from the pump is by-passed through the pressure regulating valve back to the inlet side of the pump. The quantity of fuel by-passed increases as the pump speed increases. The delivery pressure also increases with speed. Fuel not by-passed by the regulating valve passes through a hydraulic head passage to the metering valve. Fuel is metered by the metering valve in a quantity determined by engine demand.

Delivery Valve—A displacement type delivery valve is located in the drive passage of the rotor between the charging port and discharge port of the rotor. It remains closed during charging and opens under high pressure as the plungers are forced together.

End Plate—The end plate has three basic functions: 1) to provide passage for fuel and to cover and absorb end thrust of the transfer pump; 2) to house the pressure regulator valve and, 3) to house the priming by-pass spring which permits fuel to by-pass the transfer pump during hand priming, Fig. 6.

Governed Speed (High Idle)—When the engine is operating at no load governed speed, the quantity of fuel delivered is controlled by governor action on the metering valve. Leaf spring adjustment has no effect under this condition.

Part Load and Full Load—As load is progressively applied, the governor action on the metering valve continues to control the quantity of fuel delivered until engine rpm drops to rated load speed. At this point the governor has opened the metering valve sufficiently for complete plunger charging. Any further movement of the metering valve does not increase the fuel delivery. The maximum amount of fuel that can be injected at any full load speed is controlled by the roller or leaf spring adjustment.

Overload—As the engine speed continues to drop from rated load, the charge of fuel is great enough to force the plungers outward far enough during each charging cycle to bring the roller shoes into contact with the leaf spring. This prevents further outward movement of the plungers and, therefore, limits the maximum amount of fuel that can be injected. From this it can be seen that the maximum amount of fuel that can be injected during any overload operation below peak torque is controlled by the leaf spring adjustment.

Speed Advance—The injection pump incorporates a speed advance mechanism that provides for fuel injection at the most desirable time for various engine speeds. In addition it allows the engine to be started with injection retarded (from full advance position). This feature greatly aids in starting.

Since transfer pump fuel pressure increases with an increase in engine speed and decreases with a decrease in engine speed, the transfer pump fuel pressure is used to control the movement of the automatic advance power piston working against spring pressure.

Controlled movement of the cam in the pump housing is induced and limited by the action of the power piston and spring piston of the automatic advance against the cam advance screw.

During cranking the cam is in the retarded position because the force of the fuel on the power piston is not great enough to overcome the spring pressure. As engine rpm and fuel pressure increase, fuel pressure on the power piston overcomes the spring pressure, thus moving the cam to the advanced position. A check valve is used on the inlet side of the power piston to offset the tendency of the cam to return to the retarded position during each injection. *Power piston side is on the side of the pump having the letter "C" in raised print on housing.*

Fig. 5 Cutaway view of fuel injection pump

Fig. 6 Cutaway view of end plate assembly

TROUBLE SHOOTING

Fuel Not Reaching Pump

1. Electric shut-off inoperative.
2. Seizure of distributor rotor.
3. Hand primer installed backwards.
4. Engine rotation wrong.
5. Filters or strainer clogged.
6. Fuel too heavy at low temperature.
7. Transfer pump liner locating pin in wrong hole for correct rotation.
8. Transfer pump blades worn or broken.
9. Fuel lines clogged or restricted.
10. End plate regulating piston sticking in "prime" position.
11. Air leaks on suction side of system.

Fuel Delivered From Transfer Pump But Not To Nozzles

1. Shut-off device at "stop".
2. One or more connector screws obstructed.
3. Metering valve sticking or closed.
4. Governor spring worn or broken.
5. Governor linkage broken.
6. Governor not operating; parts or linkage worn, sticking or binding, or incorrectly assembled.
7. Metering valve incorrectly assembled.
8. Fuel lines clogged or restricted.

9. Cam backwards in housing.
10. Cam roller shoes sticking.
11. Plunger missing.
12. Plungers sticking.
13. Passage from transfer pump to metering valve clogged with foreign matter.
14. Rotors badly scored.

Fuel Reaching Nozzles But Engine Won't Start

1. Cranking speed too low.
2. Engine engaged with load.
3. Pump timed incorrectly to engine.
4. Throttle arm travel not sufficient.
5. Intake air temperature low.
6. Water in fuel.
7. Worn advance pistons (incorrect cam position).
8. Injection pipes leaking or connected to wrong cylinders.
9. Cam, shoes or rollers worn.
10. Maximum fuel setting at low limit or too low.
11. Excessive fuel leakage past plungers (worn or badly scored).
12. Shut-off device interfering with governor linkage.
13. Automatic advance faulty or not operating.
14. Nozzles faulty or sticking.
15. Fuel too heavy at low temperature.
16. Rotor badly scored.
17. Poor engine compression.
18. Lube oil too heavy at low temperature.
19. Low cetane fuel.

Engine Starts Hard

1. Engine engaged with load.
2. Cranking speed too low.
3. Intake air temperature low.
4. Pump timed incorrectly to engine.
5. One or more connector screws obstructed.
6. Fuel lines clogged or restricted.
7. Air leaks on suction side of system.
8. Filters or strainer clogged.
9. Fuel too heavy at low temperature.
10. Lube oil too heavy at low temperature.
11. Water in fuel.
12. Poor engine compression.
13. Low cetane fuel.
14. Transfer pump blades worn or broken.
15. End plate regulating piston sticking in "prime" position.
16. Transfer pump faulty (pressure too low).
17. Shut-off device interfering with governor linkage.
18. Metering valve sticking or closed.
19. Governor linkage out of adjustment.
20. Governor not operating; parts or linkage worn, sticking or binding, or incorrectly assembled.
21. Maximum fuel setting at low limit or too low.
22. Cam, shoes or rollers worn.
23. Plungers sticking.
24. Excessive fuel leakage past plungers (worn or badly scored).
25. Wrong advance pistons (incorrect cam position).
26. Automatic advance faulty or not operating.
27. Rotor delivery valve screw loose or leaking.
28. Nozzles faulty or sticking.
29. Engine valves faulty or out of adjustment.
30. Rotor badly scored.
31. Advance unit incorrectly adjusted.

Engine Starts and Stops

1. Fuel lines clogged or restricted.
2. Water in fuel.
3. Air intake restricted.
4. Return oil line restricted.
5. Engine overheating.
6. Filters or strainer clogged.
7. Air leaks on suction side of system.
8. Metering valve sticking or closed.
9. Transfer pump blades worn or broken.
10. Cam roller shoes sticking.
11. Plungers sticking.
12. Advance unit incorrectly adjusted.

Erratic Engine Operation: Surge, Misfiring, Poor Governor Regulation

1. Injection pipes leaking or connected to wrong engine cylinders.
2. Fuel lines clogged or restricted.
3. Filters or strainer clogged.
4. Pump timed incorrectly to engine.
5. Water in fuel.
6. Low cetane fuel.
7. Pump housing not full of fuel.
8. Air leaks on suction side of system.
9. Nozzles faulty or sticking.
10. Engine valves faulty or out of adjustment.
11. Wrong advance pistons (incorrect cam position).
12. Automatic advance faulty or not operating.
13. Metering valve sticking or closed.
14. Governor not operating; parts or linkage worn, binding or sticking, or incorrectly assembled.
15. Governor spring worn or broken.
16. Governor linkage out of adjustment.
17. Governor sleeve binding on drive shaft.
18. Governor spring rate too low.
19. Transfer pump blades worn or broken.
20. Transfer pump faulty (pressure too low).
21. End plate regulating piston sticking.
22. Rotor delivery valve screw loose or leaking.
23. Cam roller shoes sticking.
24. Tang drive worn in excess of .008".
25. Plungers sticking.
26. Advance unit incorrectly adjusted.

Engine Idles Poorly

1. Water in fuel.
2. Pump housing not full of fuel.
3. Air leaks on suction side of system.
4. Pump timed incorrectly to engine.
5. Transfer pump blades worn or broken.
6. Governor not operating; parts or linkage worn, sticking or binding, or incorrectly assembled.
7. Metering valve sticking or closed.
8. Governor linkage out of adjustment.
9. Idle spring incorrect or missing.
10. Nozzles faulty or sticking.
11. Wrong advance pistons (incorrect cam position).
12. Automatic advance faulty or not operating.
13. End plate regulating piston sticking.
14. Fuel lines clogged or restricted.
15. Low cetane fuel.
16. Governor spring wrong or broken.
17. Engine valves faulty or out of adjustment.
18. Governor linkage broken.
19. Excessive fuel leakage past plungers (worn or badly scored).
20. Plungers sticking.
21. Advance unit incorrectly adjusted.

Engine Won't Develop Full Power or Speed

1. Throttle arm travel not sufficient.
2. Shut-off device interfering with governor linkage.
3. Incorrect governor high idle adjustment.
4. Fuel lines clogged or restricted.
5. Air leaks on suction side of system.
6. Filters or strainer clogged.
7. Pump timed incorrectly to engine.
8. Return oil line restricted.
9. One or more connector screws obstructed.
10. Governor not operating; parts or linkage worn, sticking or binding, or incorrectly assembled.
11. Metering valve sticking or closed.
12. Governor linkage out of adjustment.
13. Wrong advance pistons (incorrect cam position).
14. Automatic advance faulty or not operating.
15. Transfer pump blades worn or broken.
16. Transfer pump faulty (pressure too low).
17. Maximum fuel setting at low limit or too low.
18. Cam, shoes or rollers worn.
19. Plungers sticking.
20. Excessive fuel leakage past plungers (worn or badly scored).
21. Tang drive worn in excess of .008".
22. Rotor badly scored.
23. Low cetane fuel.
24. Rotor delivery valve screw loose or leaking.
25. Water in fuel.
26. Poor engine compression.
27. Advance unit incorrectly adjusted.

Engine Smokes Black

1. Exceeding rated load.
2. Air intake restricted.
3. Engine overheating.
4. Pump timed incorrectly to engine.
5. Nozzles faulty or sticking.
6. Engine valves faulty or out of adjustment.
7. Automatic advance faulty or not operating.
8. Low cetane fuel.
9. Wrong advance pistons (incorrect cam position).
10. Poor engine compression.
11. Cam, shoes or rollers worn.
12. Maximum fuel setting too high.
13. Advance unit incorrectly adjusted.

Engine Smokes Blue

1. Engine cold.
2. Excess lube oil in air cleaner.
3. Pump timed incorrectly to engine.
4. Wrong advance pistons (incorrect cam position).
5. Automatic advance faulty or not operating.
6. Tang drive worn in excess of .008".
7. Lube oil pumping past valve guides or piston rings in engine.
8. Advance unit incorrectly adjusted.

INJECTION PUMP, REPLACE

Removal

1. Turn crankshaft so that No. 1 piston is 2° before TDC on compression stroke.
2. Clean pump of all dirt before removal.
3. Remove all fuel lines between injection pump and nozzles.
4. Disconnect fuel filter-to-pump hose. Disconnect fuel return line at pump.
5. Disconnect throttle linkage.
6. Disconnect electrical connections to solenoid terminal on pump cover.
7. Loosen two adapter plate stud nuts. *Because of limited space the top nut will have to be run off the stud as the pump is being removed from the engine.* The pump drive shaft will remain in the front plate, keyed and secured with a nut to the pump drive gear.
8. Plug fuel inlet and return openings to keep dirt out of pump and discharge ports. *If pump requires service it should be returned to an authorized International dealer.*

Installation & Timing

1. Before installing pump on engine, check condition of drive shaft oil seals and replace if necessary.
2. Note the position of the small hole drilled in the end of the pump drive shaft. Likewise note the position of the hole drilled in the end of the distributor rotor. *These holes must meet when the pump is installed correctly. If they do not meet, use a clean screwdriver and turn the rotor to align the holes.* It is assumed that the engine has not been disturbed since removing the pump.
3. Position the pump and use a suitable tool to compress and protect the seal when installing the pump. Using a "wringing" motion while pushing on the pump, lead the pump on the shaft and past the seals. *The top stud nut and washer will have to be placed on the stud before the pump is tight against the front plate because of limited space.* Before tightening the nuts, remove the timing line window cover and if the marks are not aligned, rotate the pump housing until they are aligned, then tighten the two pump stud nuts. *Do not attempt to time pump while engine is running.*
4. Install fuel lines between pump and nozzles. Be sure copper washers are in place on each side of banjo fittings.
5. Connect hose from pump to filter, and connect fuel return line.
6. If engine has been moved while pump was off, retime as follows:
7. Turn engine over until No. 1 piston is 2° before TDC on the compression stroke. The timing pointer should indicate 2° advance on pulley calibration. Be sure this setting is established before installing pump.
8. Install the pump as outlined above. To be sure the installation is correct, remove the pump gear inspection cover and note the position of the timing marks on the gear hub and sleeve. A separation of approximate $\frac{3}{32}$" between the marks will be normal. These marks should be at the "5 o'clock" position.
9. Remove the timing window from the pump. The timing line on the cam must be lined up with the line on the governor weight retainer. If the line on the governor weight retainer does not show at all, the retainer is 180° out of time. To correct, the governor weight retainer should be installed over the rotor so that the stamped mark in the retainer is lined up with the stamped mark on the rotor.

Fig. 7 View through plastic timing window

VENTING FUEL SYSTEM

Whenever the fuel pump or fuel lines have been removed the system should be vented as follows:

1. Open the vent valves on the fuel filters and hand prime the system until fuel flows from the vents; then close the valve.
2. Continue hand-priming until fuel flows from the fuel by-pass fitting in the injection pump cover; then tighten this connection.
3. Try starting the engine *but do not crank with the starting motor for more than 30 seconds at a time.* If the engine does not start, loosen the fuel pipe nuts at No 1 and No. 2 injection nozzles (use two wrenches). Crank the engine until fuel appears. Tighten the nuts and try starting the engine again. If the engine still won't start, bleed air from the other four injector lines in the same manner.

NOZZLE TESTING

Carefully clean the fuel line connections at each nozzle. Disconnect them one at a time and attach a flexible hose from a test pump to the nozzle fitting. Install a pressure gauge of at least 1500 psi on the test pump. Operate the test pump to bring the pressure rapidly up to the opening pressure (850-1050 psi). Valve seat leakage should not occur below 700 psi. This seat leakage will be indicated by a dropping off of the pressure within a short period of time.

An injection service mechanic should make prior studies, using nozzles he may have encountered in the field, and learn the pressure gauge indications for a good nozzle as compared with a nozzle which is operating poorly.

The distinctly different gauge action is easy to detect, and a mechanic can become experienced in "blind analysis" of nozzles very quickly. Proceed to test each nozzle, recording opening pressure, chatter condition, and leakage rate when pressure is brought up to within 100 psi of opening pressure. If sufficient cause is found at this point for poor performance reported, the search can end and necessary repairs made.

FUEL KNOCK

Fuel knock is often noticeable when a nozzle is leaking into the cylinder. It is a loud noise similar to a piston slap. To locate an engine fuel knock, loosen the fuel line connection (use two wrenches) at each nozzle. This will cut off fuel flow to that cylinder. If pre-ignition is the cause of the knock, the noise will cease when the faulty nozzle is disconnected.

ELECTRICAL SHUT-OFF DEVICE

Fuel is allowed to flow through the injection pump when an electrical solenoid located in the pump housing cover is energized to run. De-energizing the solenoid allows the shut down coil spring to open the shut down arm. The lower end of the arm moves a governor linkage hook, which rotates the metering valve to the closed position, cutting off the fuel.

ADJUSTMENTS, PUMP ON ENGINE

Improper timing or faulty operation of the speed advance mechanism can cause one or more of the following conditions: hard starting, misfiring at speeds between 1500 and 3000 rpm. loss of power, increased fuel consumption.

Static Injection Timing

1. With engine shut down, install the special plastic timing window, SE-1999-4, Fig. 7. Note the location of the cam timing line. *Due to variations in plastic windows, hole locations and basic pump specifications, the cam line might not be exactly behind the center window line.*
2. Turn engine over in normal direction of rotation until the timing line on the governor weight retainer aligns with the cam center line, Fig. 7. Note the timing mark on the crankshaft pulley indicated by the pointer on the front cover. *Do not attempt to time pump while engine is running.*

Maximum No Load Governed Speed

With engine running at normal operating temperature, hold the throttle lever all the way to the rear. Adjust the

Fig. 8 Adjusting governed speed stop screw

Fig. 9 Adjusting idle speed stop screw

Fig. 10 Adjusting idle speed bumper

Fig. 11 Adjusting advance trimming screw

governed speed stop screw, Fig. 8, until the specified speed is obtained.

Idle Speed

With engine running at normal operating temperature, back out the guide stud as indicated in the idle bumper adjustment below. Then hold throttle lever all the way forward and adjust the idle stop screw, Fig. 9, until specified idle speed is obtained.

Idle Bumper

Idle bumper controls idle surge and prevents stall on deceleration. Adjust as follows with engine at normal operating temperature; Fig. 10.

1. Back out guide stud (bumper) so that approximately four threads show beyond lock nut.
2. Adjust idle stop screw to obtain specified rpm.
3. Turn guide stud in until speed increases 10 to 30 rpm.
4. Back guide stud out 1/12 turn and lock. With guide stud in this position, there should be a slight gap between bumper assembly and governor arm. If idle surge or stalling occurs guide stud can be adjusted "in" slightly.

Advance Unit

Before starting engine, note cam line position. This will be the retard position. Warm up engine. At 1000 rpm cam should be in retard position. Increase speed to maximum governed no load speed, at which time cam should be in full advance (lowest) position. If advance does not meet with specifications, adjust advance trimming screw, Fig. 11. Replace timing window with cover plate and gasket.

After all the foregoing checks, if the speed advance is not operating properly, check the transfer pump for low pressure. Also check for seized advance pistons, seized cam, dirt, wear or corrosion. When any of these conditions exist, the pump must be removed from the engine and serviced by an authorized International establishment.

ENGINE, REPLACE

The engine may be removed from the chassis as an assembly complete with accessories. Only the air cleaner need be removed. The transmission is separated from the engine at the flywheel housing. Drain cooling system and crankcase. Disconnect battery ground cable and tape end of terminal to prevent accidental grounding.

Fig. 12 Cylinder head tightening sequence

On conventional models, only the hood, fan and radiator need be removed before the engine can be lifted out of the chassis. Remove the hood hinge bracket mounting bolts from the cowl and lift off the hood. Remove upper and lower hoses. Remove fan and pulley. Unfasten and remove radiator and fan shroud.

On forward control models, it will be necessary to remove hood, fenders, shell and radiator from chassis.

Disconnect Points On Engine

1. Fuel inlet and fuel by-pass line from fuel injection pump.
2. Throttle control lever at pump.
3. Exhaust pipe at manifold.
4. Wiring harness from generator, starter, glow plug terminal, fuel shut-off terminal on pump, and temperature sending unit (all on right side of engine) and from oil pressure sending unit on left side of engine.
5. Vacuum line from vacuum pump.
6. Tachometer drive cable from oil pump shaft support on left side of engine.
7. Engine ground strap.
8. After removing engine front mountings and separating flywheel housing from engine, attach lifting rig and remove engine from chassis.

CYLINDER HEAD

Cylinder heads should be tightened in the sequence shown in Fig. 12 and to the proper torque (given in *Engine Tightening* table). Do not tighten to full torque the first time around; it is advisable to tighten to full torque in three steps.

Re-tighten the cylinder head after the engine has been operated for 50 to 100 hours. Then only those bolts below proper torque are to be tightened to specifications.

Fig. 13 Rocker arm assembly

ROCKER ARMS

The rocker arm assembly, Fig. 13, is composed of front and rear shafts, joined at the center, on which are mounted 12 rocker arms and six tension springs. The shafts are mounted in seven brackets and are prevented from turning by grooves in the ends of the shafts.

Separate the shafts and slide off the rocker arms, springs and brackets. The No. 2, 4 and 6 (front to rear) rocker arm brackets have sleeve dowels which keep the rocker arm assembly aligned. The three hold-down brackets are reamed from the bottom side so that the sleeve dowels will fit tight into the brackets. About half of the dowel is in the bracket, the remaining half fits into the head. When removing the rocker arm assembly, the dowels will remain in the hold-down brackets.

All six intake rocker arms are alike. However, there are three left-hand and three right-hand exhaust rocker arms and three different types of rocker arm brackets. Four of the rocker shaft brackets are of one type and are used in positions 2, 4, 5, and 6, Fig. 13. These brackets are drilled and reamed to accept the sleeve dowel. The bracket used in position 3 contains an enlarged bolt hole, and is used as the oil supply inlet for the rocker arm assembly.

VALVES, ADJUST

To adjust valve lash, each cylinder must be brought up to top dead center on its compression stroke when adjusting valves for that cylinder. To determine the correct position, turn the engine crankshaft until No. 1 piston is at top dead center on its compression stroke and stop when the TDC mark on crankshaft pulley is in line with the pointer on the timing case cover.

Adjust each valve to the clearance given in the *Valve Specifications* table and then, turning over the engine according to its firing order progressively, adjust the remaining valves.

After the engine has run long enough to bring it to operating temperature, recheck and, if necessary, adjust the clearances.

VALVES, REMOVE

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

VALVES, GRIND

Fig. 14 illustrates the recommended valve seats to be obtained. The intake seats may be narrower than the exhaust because they are usually larger in diameter, thus providing a total seat area approximately equal to smaller exhaust valve with the wider seat. Also the less severe heat conditions do not require as large a seat area for heat dissipation purposes.

Fig. 14 Valve seat widths

There are also objections to an excessively wide seat. In city or light delivery service, a wide seat collects carbon and particles of dirt that will produce variations or loss of compression, resulting in poor idle and possibly a loss of general performance and economy.

A wide seat in severe service, operating in the presence of dirt or an excess of carbon, will produce a badly pitted seat which may be just as detrimental to valve life as a too narrow seat. Under these conditions, a seat width to the minimum limit would possibly be better. However, the source of trouble (dirt, carbon) should be eliminated, making it possible to retain the wider seat.

VALVE SEAT INSERTS

If replacement of a valve seat insert becomes necessary, it is important that the new insert be securely peened in place, using either an insert peening tool or a dull-pointed chisel, ¼" wide, to peen the cylinder head or block metal over the outer edge of the valve seat insert.

Valve seat inserts supplied for service are standard size and .030" oversize which permits a tight fit.

VALVE SPRINGS

Valve springs should be checked by measuring their free length, and the uniformity should not vary more than $\frac{1}{16}$".

Each spring should also be checked for squareness. This can be done with a steel square and surface plate. Stand each spring and the square on end on the surface plate and slide the spring up to the straight edge of the square. Then gradually revolve the spring, while at the same time noticing the space between the top coil of the spring and the square. This space should not exceed $\frac{1}{16}$"; if more, replace the spring.

Valve springs should be checked for tension with a spring tester. Any spring that does not conform to the specifications listed in the chart within 10% should be replaced.

VALVE GUIDES

Clean valve guides with a suitable cleaning tool. Then check each valve guide with a "GO and NO-GO" gauge, if available; otherwise, use a new valve to check the fit. If the "NO-GO" portion of the gauge enters, the guide must be replaced.

Clearance in excess of .006" for intake valves and .008" for exhaust valves, calls for replacement of valve guides.

New guides should be installed so that the distance from the cylinder head to the top of the guide is .938".

VALVE LIFTERS

Valve lifters or tappets are of the barrel type, operating in guide holes bored in the cylinder block. The lifters can be lifted out of the block after taking off the engine side cover and removing the push rods.

TIMING GEAR COVER

1. To remove cover, remove fan, belts and water pump.
2. Position No. 1 piston on top dead center of the compression stroke. *Remove glow plugs before cranking engine.*
3. Remove generator.
4. Remove oil cooler hoses.
5. Remove engine front support.
6. Remove crankshaft end nut and washer.
7. Remove fan drive pulley and damper with a suitable puller.
8. Remove two front oil pan bolts in front cover.
9. Unfasten and remove cover, gasket and crankshaft oil slinger.
10. Reverse foregoing procedure to install cover.

TIMING GEARS

Before removing any gears, it is advisable to check the backlash and end play of the gears to determine which, if any, require service. Backlash between injection pump gear and idler gear should be .003" to .009"; between idler gear and crankshaft gear .003" to .006"; between camshaft and crankshaft gears .003" to .006". If gears are to be removed, proceed as follows:

1. Remove injection pump gear and shaft, being careful not to drop or lose the thrust button or spring inside the button.
2. Remove injection pump.
3. When camshaft gear is removed, do not turn crankshaft without first backing off all the valve lash adjusting screws. This is to relieve the rocker arms and allow all valves to seat, thereby avoiding damage by piston up-strokes.
4. Install puller and remove camshaft gear.

5. Remove camshaft thrust plate.
6. Remove idler gear and shaft.
7. Remove crankcase front plate.
8. Remove crankshaft gear.

Installation Note

For correct valve timing, align the single punch mark space on the camshaft gear with the single punch marked tooth on the crankshaft gear, Fig. 15.

Install the idler gear, being certain to match the double punch mark space on the crankshaft gear with the double punch mark on the tooth of the idler gear. When installing the shaft, align the oil hole in the shaft with the hole in the front plate, and the locating pin with the hole in the front plate. The lower hole is the oil hole.

Install the injection pump gear, lining up the single punch mark tooth of the gear with the single punch mark space of the idler gear.

When installing the injection pump, refer to the instructions under that heading.

CAMSHAFT & BEARINGS

The camshaft is located in the crankcase on the right-hand side of the engine and is held in position by a thrust plate. The camshaft is supported along its length by four bushings. The bushings are removable and are furnished for service reamed to size.

The camshaft bearings are pressure lubricated and have oil holes drilled in them. When the bushings are installed, the oil holes must be aligned with the ones drilled in the crankcase. Slots in the camshaft permit lubricating oil travel to the valve mechanism.

PISTONS & RODS, ASSEMBLE

Pistons are assembled to the connecting rods so that when installed in the cylinders the front of the piston will be indicated by the letter "F" and the numbered side of the rod will be on the camshaft side of the engine.

PISTONS & CYLINDERS

Measure the piston skirt at right angles to the pin to determine if it is worn excessively. Each cylinder bore should be checked with an inside reading micrometer to determine taper, out-of-round or worn condition. Measure the diameter of the cylinder at the top of the piston ring travel at a right angle to the centerline of the crankshaft. Record the readings. Next, measure each bore so the gauge reading coincides with the centerline of the crankshaft. The difference between the readings is the out-of-round condition at the top of the bore.

Repeat this procedure at the bottom of the ring travel. The difference between the diameters measured at the top and bottom of the bore is the taper of the bore. Rebore cylinders if worn beyond .008", and fit new pistons to the clearance specifications given in the chart.

Fig. 15 Matching timing gear marks

PISTON RINGS

Always use standard size rings in cylinder bores that are standard at the bottom of the ring travel, regardless of the amount of taper in the bore. Oversizes must be determined by the measurement of the narrowest portion of the bore.

New rings should be fitted according to the instructions furnished with the ring package. Ring grooves must be clean and free from carbon and must show no perceptible wear.

PISTON PINS

To remove the piston pins, heat the piston in boiling water or a piston heater. Place the piston in a piston vise and, using a pin driving tool, drive the pin from the piston and connecting rod.

With the piston pin at room temperature (70°) and coated with clean engine oil, and the piston heated in hot water to approximately 150°, the pin can be entered into one boss of the piston by pushing with the hand. While the piston is hot, quickly and correctly position the connecting rod inside the piston, align the bushing in the rod bore with the piston holes in the piston and push the pin completely into position. Thoroughly dry the piston with compressed air. Install a retainer ring in the groove at each side of the piston to secure the pin.

ROD BEARINGS

These bearings are of the precision insert type, requiring no scraping or reaming.

When installing bearings, be sure the back of the bearing shells as well as the bearing seats in the rods are smooth and clean.

Bearing clearance may be checked with Plastigage, which is available at any auto parts jobber. Instructions for its use are furnished with the package.

Lacking Plastigage, however, use a piece of tough paper or shim stock ¾" square which measures about .0005" under the maximum allowable bearing clearance. Oil the shim on both sides and lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap bolts to normal tension.

The clearance is correct if the rod can be moved endwise when tapped lightly with a hammer. If the rod can be moved endwise by hand, clearance is too great. On the other hand, if the rod will not move when tapped lightly with a hammer, not enough clearance is present.

When using a torque wrench tighten bearing caps to the torque loads given in the table.

MAIN BEARINGS

These bearings are of the insert type, requiring no reaming or scraping. They may be removed and replaced without removing the crankshaft.

Plastigage may be used to check bearing clearances, and instructions for its use are furnished with the package.

Lacking Plastigage, an alternate method is to use a piece of tough paper or shim stock 1" square which measures about .001" under the maximum allowable bearing clearance. Oil the shim on both sides and lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap bolts to normal tension.

Rotate the crankshaft through a two-inch arc (one each way) and if it is movable with a fairly heavy drag, the clearance is correct. If there is no perceptible drag, the clearance is too great. On the other hand, if the shaft cannot be moved, not enough clearance is present.

Be sure that the bearings are smooth and clean on both sides when installed. This applies to the bearing seats as well.

When using a torque wrench, tighten bearing caps to the torque loads given in the table.

CRANKSHAFT REAR SEALS

The following procedure should be followed for proper installation of the rear main bearing cap, seal and sealing plugs:

1. With special aligner dowels in place, Fig. 16, rear main bearing cap bolts should be installed finger tight only.
2. Place seal on installer tool, Fig. 17.
3. Install oil seal over crankshaft flange with special tool and start seal into bearing cap crankcase bore. *Caution: ⅛" of seal must project back of* crankcase rear face.
4. Torque the four bearing cap bolts to recommended torque and remove the two aligner dowels.
5. Place the sealing plug installer, Fig. 18, into sealing plug and lubricate

Fig. 16 Lining up rear main bearing cap by means of aligner dowels

Fig. 17 Placing crankshaft rear seal on installer tool

outside of plug for ¾ of its length with quick-setting grease. *Do not allow plugs to set in free state after coating with grease.*

6. Push sealing plug into place until underside of plug flange is flat against pan rail.
7. Remove insert tool by giving half twist and then pulling out.
8. Use installing tool and press seal to its final location, Fig. 19.

OIL PUMP

A conventional gear type oil pump, located in the crankcase, is used. After removing the oil pan, the pump may be unfastened from its mounting and disassembled for repairs.

Inspect the pump gears for nicks or burrs. Inspect the bottom cover for wear and dress down on a surface plate with emery if necessary. Place the bottom cover on the pump and check the drive shaft end play. If end play is excessive (more than .006"), replace the drive and idler gears.

Fig. 18 Installing sealing plugs

OIL PUMP SHAFT SUPPORT

The oil pump shaft support, located on the left side of the engine, gives rigid mounting to the pump shaft and serves as a tachometer drive housing. The support will require little more than periodic maintenance. However, if excessive wear of the pinion or bushings is indicated the assembly can be disassembled and repaired. When servicing the support, refer to Fig. 20.

OIL COOLER

The oil cooler is mounted on the left side of the engine to the oil filter base. Two plugs are located in the oil manifold to allow draining the oil, and one plug is located in the bottom of the oil cooler to drain the cooler of water.

Improper care of the cooling system and lubricating oil system are the most probable reasons for poor engine oil cooler performance. When the cooler requires attention, remove and disassemble it; then immerse all parts in cleaning solvent to loosen any sludge or foreign matter. Drain and blow out any solvent and foreign matter inside the oil cooler and oil manifold. Be certain that all passages are clean and clear before reassembly.

Installation

1. Using a new gasket, secure oil cooler assembly to oil filter base.
2. Install and secure two hoses to oil cooler.
3. Install or close all cooling system and lubricating oil system drain plugs or valves, including the drain plug in the filter base.
4. Fill the cooling system.
5. Add one quart of the proper grade engine oil to the crankcase.
6. Run engine to refill filter and oil cooler.
7. Stop engine and check thoroughly for leaks. Also check crankcase oil level.

WATER PUMP

The pump used on these engines is of the sealed ball bearing type packed with lubricant at the time of assembly and requiring no further lubrication. When disassembling, carefully note the arrangement of the seal parts so that correct assembly may be assured, Fig. 21.

Never soak the shaft and bearing assembly in cleaning solvent because it will dissolve the lubricant. To clean the shaft and bearing, merely moisten a cloth with cleaning fluid and wipe away any surplus lubricant or other foreign matter.

Be sure the face of the housing against which the thrust washer turns is smooth and true. If not, smooth it up with a special water pump facing cutter.

MODEL INDEX & ENGINE APPLICATION

ENGINE IDENTIFICATION—Engine model takes the form of a prefix to the engine serial number. For example, a V-266 engine serial number would read V-266-000000. Engine numbers are located on machined boss on cylinder block.

① Stamped on plate riveted to housing. ② Viewed from top. ③ Measured from center of contact.

Engine Section

ENGINE, REPLACE

LPG Warning

If the truck is equipped with LPG fuel system, be sure that the tank valves are tightly closed and all fuel exhausted from the lines before starting any repair work on the fuel system.

Any trucks of this type which have been involved in an accident should not be brought into the shop for repair until the tanks and system is checked for possible leaks.

V8 Engines

The engine is removed as an assembly complete with accessories, less the carburetor air cleaner. The transmission is separated from the engine at the flywheel housing. Drain the cooling system; drain points are located one on each side and toward the front of the cylinder block and the lower left of the radiator. Drain engine oil. Disconnect battery ground cable and tape the end of the terminal to avoid accidental grounding.

On V8-401, 461, 549, tapped holes at the rear of the intake manifold and engine front cover are provided for lifting eye bolts.

On V8-266, 304, 345, the engine lifting fixture can be attached to the intake manifold by utilizing the carburetor mounting capscrews with flat washers. *When installing the lifting fixture, the capscrews are to be installed finger tight; then tighten the capscrews one-half additional turn.*

BD-269, 282, 308. Dry-Type cylinder liners used in 269 engine only

4-152 Engine

1. Drain cooling system, crankcase and disconnect battery ground cable.
2. Remove fan blade, radiator, and other parts such as radiator cross braces, heater air ducts, etc., which may interfere with engine removal.
3. Remove carburetor and engine wiring.
4. Remove fuel line from pump.
5. Disconnect exhaust pipe from manifold.
6. Install lifting fixture on engine.
7. Hoist engine enough to support it while disconnecting engine front mountings.
8. Separate engine from transmission by separating transmission from flywheel housing or flywheel housing from rear of engine.
9. Pull engine forward to clear clutch from transmission main drive gear shaft. Then tilt engine upward and remove from chassis.

A-55 Engine

To remove the engine the transmission must first be removed since the engine rear support is dependent on the transmission.

1. Place truck front end on floor jacks and remove floor panel directly over transmission.
2. Drain cooling system, disconnect both battery cables, remove radiator and heater hoses, wiring harness from engine, and engine ground strap.
3. Disconnect throttle lever and choke control from carburetor, and fuel inlet line to fuel pump.
4. Disconnect exhaust pipe from manifold.
5. Remove gearshift control rods from transmission. *It will not be necessary to disconnect fluid line from clutch operating slave cylinder if slave cylinder itself is removed from clutch operating lever on side of transmission.*
6. Disconnect speedometer cable from transmission, and forward end of propeller shaft.
7. If one is available, extend boom of floor crane through right side door of truck and fasten chain sling to bolts on top of cylinder head (air cleaner must first be removed). Adjust crane to support engine weight.
8. Place jack under transmission and remove transmission crossmember.
9. Unfasten transmission housing from engine rear plate and remove transmission from chassis.
10. Unfasten engine from front mounting brackets (8 bolts) and take engine out through side door.
11. Installation is made by reversing the removal procedure.

BD & SD Engines

After removing the transmission, the engine can be lifted from the chassis without disturbing the fender and grille assembly by using a suitable chain sling and floor crane.

1. Drain engine oil and cooling system.
2. Disconnect upper and lower hoses.
3. Remove air cleaner and disconnect vacuum pipe from manifold.
4. Disconnect coil wire, starter cable, engine ground strap, and instrument sender unit wires.
5. Disconnect fuel line at fuel pump.
6. Disconnect throttle control linkage and remove choke wire at carburetor.
7. Disconnect clutch linkage at bell housing.
8. Remove engine rear mounting bolts from both sides of engine support pads.
9. Remove engine front mounting bolts from support bracket (these are the bolts at the front cross member). The engine front bracket is removed with the engine.
10. Unfasten radiator from its mounting and lift out radiator and its support.
11. Disconnect exhaust pipe at manifold.

12. Remove engine from chassis.
13. Replace in reverse order of removal.

RD Engines

1. Drain engine oil and cooling system.
2. Disconnect upper and lower hoses.
3. Remove air cleaner.
4. Disconnect vacuum line at manifold or air line at compressor when equipped with air brakes.
5. Disconnect coil wire, starter cable, engine ground strap and instrument sender unit wires.
6. Disconnect fuel line at fuel pump.
7. Disconnect throttle control linkage and remove choke wire at carburetor.
8. Remove hood and floor boards.
9. Remove fenders and grille as a unit.
10. Unfasten and remove radiator and its support.
11. Remove engine front mounting bolts from support bracket. These are the bolts at the front cross member.
12. Support transmission with floor jack or blocking. Then remove cap screws from around bell housing.
13. Disconnect exhaust pipe from manifold.
14. Attach engine sling to front and rear right side cylinder head bolts and remove engine from chassis.
15. Reverse the foregoing to install.

CYLINDER HEAD, REPLACE

All Engines

Cylinder heads should be tightened down by starting from the center, working outward from side to side and to the ends in the sequence shown in Figs. 1 to 6. Draw the bolts down evenly, repeating the operation until all are normally tight. After running the engine to warm it up thoroughly, a final tightening should be made with a torque wrench to the torque load listed in the *Tune Up & Valve Specifications* table.

ROCKER ARM SERVICE

4-152 Engine

As shown in Fig. 6A, the rocker arm assembly consists of the shaft, shaft supports, rocker arms and spacers. The rocker arms are lubricated by oil supplied to the hollow shaft through an oil passage in one of the supports.

Formation of sludge in the oil passages of the rocker arms and shaft will restrict flow of oil to the rocker arm bushings and valves. Therefore, each time the assembly is removed, it should be disassembled and cleaned thoroughly.

When disassembling, keep parts in order to assure reassembly in their original position if in satisfactory condition.

If necessary to remove plugs from each end of shaft, drill or pierce one plug, then knock out the opposite plug with a steel rod. Working from other end, knock out other plug.

When reassembling, lubricate rocker arm bushings with engine oil. Make sure the notches at ends of rocker arm shaft are up. Be sure to position the rocker arm support having the oil feed hole so that the oil hole will index with the oil feed hole in the cylinder head (third from rear, Fig. 6B).

Fig. 1 Cylinder head tightening sequence. BD 220, 240, 264 and SD engines

Fig. 2 Cylinder head tightening sequence. BD 269, 282, 308 engines

Fig. 3 Cylinder head tightenening sequence. RD engines

Fig. 4 Cylinder head tightening sequence. V-401, 461, 549

Fig. 5 Cylinder head tightening sequence. A-55 engine

Fig. 6 Cylinder head tightening sequence. 4-152, V-266, 304, 345

Service Note

Before installing push rods in 4-152 engines, rotate the crankshaft to position the crankshaft pulley hub as shown in Fig. 6B. This is to prevent possible damage to engine parts if the hydraulic lifters have not leaked down to operating position.

A-55 Engine

When servicing the rocker arm assembly, clean the shaft thoroughly and blow out all oil passages. Remove threaded plug from end of shaft.

Inspect shaft, rocker arms and bushings for wear. Replacement bushings are available for rocker arms.

Install shaft plug, rocker arms, brackets and springs in their original positions on the shaft. Lock the shaft in position with set screw. Install plain washers, spring washers and cotter pins at each end of shaft. Coat complete assembly with engine oil.

V-266, 304, 345 Engines

When assembling the rocker arms, Fig. 7, make sure the notches at the end of the rocker arm shaft are facing upward. Also make sure the rocker arm shaft support incorporating the oil feed hole is located *third from rear on right bank and third from front on left bank.*

Rocker arm shaft assemblies are interchangeable from one bank to another. Make sure rocker arms are correctly positioned to actuate the valves. Check all push rods for straightness by rolling on a flat surface. Replace any that are bent or have loose ends.

V-401, 461, 549 Engines

The rocker arm assemblies, Fig. 8, are removed from the engine as a unit. After removing the hair pin retaining rings and spring washers from the ends of the shaft, the shafts may be stripped of arms, springs and supports. Keep parts in order so they may be replaced in their original position if in satisfactory condition. Remove plugs from ends of shafts and clean all parts thoroughly, making sure all oil passages are open.

When assembling, make sure rocker arms are correctly positioned to actuate the valves. Be sure the rocker arm end supports incorporate the dowel sleeves for alignment to cylinder head.

BD Engines

The rocker arm assembly, Fig. 9, is composed of front and rear shafts joined at the center, on which are mounted twelve rocker arms and six tension springs. The shafts are mounted on seven brackets, and are prevented from turning at the two end brackets by slots in the shaft into which the cylinder head bolts fit. *Note that the left front head bolt is drilled just above the thread with an oil hole which supplies oil to the rocker arms.*

Separate the shafts and slide rocker arms, springs and brackets from the shafts. Clean all sludge and carbon deposits from the oil holes and slots.

Inspect the valve stem contact pad surface of the rocker arm and resurface if wear is perceptible. Do not remove more than .010" of material when resurfacing.

If new bushings are required in the rocker arms, press them in and burnish them into place with a burnishing tool.

Fig. 6A Rocker arm assembly on 4-152 engine

Fig. 6B Correct position of crankshaft pulley when installing push rod on 4-152 engine

Fig. 7 Rocker arm assemblies. V-266, 304, 345

Then ream the bushings to provide a clearance of .0015-.004". Ream dimension is .7505-.7520".

Inspect the tension springs for breakage or loss of tension, and replace any that show damage or loss of tension.

RD Engines

The rocker arm assembly, Fig. 10, is composed of front and rear shafts joined at the center, on which are mounted the twelve rocker arms and four tension springs. The shafts are mounted on seven brackets, and are prevented from turning at the two center brackets which contain locking washers fitting into slots in the shaft. *Note that the third bolt from the rear on the left side of the cylinder head is drilled with an oil hole which supplies oil to the rocker arms.*

Inspect the component parts of the assembly as outlined for BD engines. And when new bushings are installed in the rocker arms they should be burnished and reamed to provide a clearance of .0015-.004". Ream dimension is .8745-8760".

Fig. 8 Installation of rocker arms. V-401, 461, 549

Fig. 9 Rocker arm assembly. BD engines

Fig. 10 Rocker arm assembly. RD engines

SD Engines

The rocker arm assembly is composed of front and rear shafts joined at the center, on which are mounted twelve rocker arms and six tension springs. The shafts are mounted in seven brackets, and are prevented from turning at the two end brackets by slots in the shaft into which the cylinder head bolts fit.

Number two, four and six rocker arm brackets have sleeve dowels which keep the rocker arm assembly aligned, Fig. 11. These three hold-down brackets are reamed from the bottom side so that the sleeve dowels will fit .0015-0035" tight in the brackets. The remaining half of the dowel is fitted .0025-.0055" loose in the cylinder head.

Inspect the component parts of the assembly as outlined for BD engines. If rocker arm bushing clearance exceeds .004", press in, burnish and ream new bushings to provide .0015-004" clearance.

VALVES, ADJUST

A-55 and 6-Cyl. Engines

To adjust valve lash, each cylinder must be brought up to top dead center on its compression stroke when adjusting valves for that cylinder. To deter-

mine the correct position, turn the engine crankshaft until No. 1 piston is at top dead center on its compression stroke and stop when the ignition mark on crankshaft pulley or flywheel is in line with the pointer on the timing case cover or flywheel housing. (Flywheel on SD, pulley on all others).

Adjust each valve to the clearance given in the *Tune Up & Valve Specifications* table and then, turning over the engine according to its firing order progressively, adjust the remaining valves.

After the engine has run long enough to bring it to operating temperature, recheck and, if necessary, adjust the clearances.

Fig. 11 Details of valve mechanism. SD engines

VALVES, REMOVE

All Engines

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

VALVES, GRIND

All Engines

Fig. 12 illustrates the recommended valve seats to be obtained. The intake seats may be narrower than the exhaust because they are usually larger in diameter, thus providing a total seat area approximately equal to smaller exhaust valve with the wider seat. Also the less severe heat conditions do not require as large a seat area for heat dissipation purposes.

There are also objections to an excessively wide seat. In city or light delivery service, a wide seat collects carbon and particles of dirt that will produce variations or loss of compression, resulting in poor idle and possibly a loss of general performance and economy.

A wide seat in severe service, operating in the presence of dirt or an excess of carbon, will produce a badly pitted seat which may be just as detrimental to valve life as a too narrow seat. Under these conditions, a seat width to the minimum limit would possibly be better. However, the source of trouble (dirt, carbon) should be eliminated, making it possible to retain the wider seat.

VALVE ROTATORS

SD & RD Engines

The parts involved in the rotating mechanism are special spring seat retainer, a pair of flat halfmoon keys, a close fitting cap located on the valve stem, and a specially constructed valve stem, Fig. 13.

In order to accommodate valve expansion, the valve lash must be maintained. When camshaft rotation causes this lash or clearance to be taken up, the cap on the valve stem causes the valve keys to lower the spring retainer, removing the load of the valve springs from the valve *before* the valve is raised from its seat. A clearance of .001-.005″ on SD and .002-.006″ on RD engines should be maintained between the end face of the valve stem and cap, Fig. 9. This is the distance the spring retainer is lowered *before* the valve is moved. The slow valve rotating motion is caused by vibration of the valve, the flowing of exhaust gases around the valve head, and a slight rotating motion imparted to the valve by the valve spring.

Whenever valve work is done, check the clearance, using the special gauge shown in Fig. 14. If there is no clearance, grind off the end of the valve stem. If the clearance is too great, grind off the open end of the valve cap.

4-152 Engine

Fig. 14A illustrates the valves and related parts. Note the "Roto Cap" used with the exhaust valve.

If the special gauge is not available, a check for clearance can be made by hold-

Fig. 12 Valve seat widths. All engines

Fig. 13 Rotating exhaust valve mechanism. SD and RD engines

Fig. 14 Showing use of special gauge for checking clearance between valve stem and cap. SD and RD engines

Fig. 14A Valves and related parts on 4-152 engine

Fig. 15 Magnified view showing how cylinder head or block metal should be peened to secure valve seat insert in place

ing the assembled valve and rotating mechanism in the hands. With one hand press down on the valve cap and with the other hand turn the valve. If the valve turns readily at least it indicates that there is clearance present.

VALVE SEAT INSERTS

Not Used On A-55

If replacement of a valve seat insert becomes necessary, it is important that the new insert be securely peened in place, Fig. 15, using either an insert peening tool or a dull-pointed chisel, ¼″ wide, to peen the cylinder head or block metal over the outer edge of the valve seat insert.

Valve seat inserts supplied for service are standard size and .030″ oversize which permits a tight fit.

VALVE SPRINGS

Valve springs should be checked by measuring their free length, and the uniformity should not vary more than $\frac{1}{16}$″.

Each spring should also be checked for squareness. This can be done with a steel square and surface plate. Stand each spring and the square on end on the surface plate and slide the spring up to the straight edge of the square. Then gradually revolve the spring, while at the same time noticing the space between the top coil of the spring and the square. This space should not exceed $\frac{1}{16}$″; if more, replace the spring.

Valve springs should be checked for tension with a spring tester. Any spring that does not conform to the specifications listed in the chart within 10% should be replaced.

VALVE GUIDES, REPLACE

Clean valve guides with a suitable cleaning tool. Then check each valve guide with a "GO and NO-GO" gauge, if available; otherwise, use a new valve to check the fit. If the "NO-GO" portion of the gauge enters, the guide must be replaced.

Clearance in excess of .006″ for intake valves and .008″ for exhaust valves, calls for replacement of valve guides.

New guides should be installed so that the distance from the cylinder head to the top of the guide is as follows.

4-152 intake	$\frac{31}{32}$″
4-152 exhaust	$1\frac{3}{32}$″
A-55	⅝″
V-266	$\frac{31}{32}$″
V-304, V-345 Intake	$\frac{31}{32}$″
V-304, V-345 Exhaust	$1\frac{3}{32}$″
V-401, 461, 469	1″
BD-220, 240, 264 Fig. 16:	
To Eng. No. 605593	$1\frac{7}{32}$″
Starting at Eng. No. 605593:	
Intake	1⅛″
Exhaust	¾″
BD-269, Fig. 16	$1\frac{1}{16}$″
BD-282, 308:	
To Eng. No. 170020	$1\frac{1}{32}$″
Starting at Eng. No. 170020:

BD 282, 308	.3735-.3755"
SD	.3743-.3758"

VALVE LIFTERS

4-152 & V8 Engines

Hydraulic valve lifters, Figs. 18, 19, are removed from the engine as an assembly. The lifters are removed by removing the valve cover, rocker arm and shaft assembly, then lifting out the push rods. If a lifter cannot be removed due to carbon build-up, use a carburetor solvent in the lifter bore. However, if an excessive amount of solvent is used, it will be necessary to change the engine oil. The lifters are also accessible by removal of the lifter covers.

As shown in Figs. 18, 19, different designs of hydraulic lifters are used. When disassembling, do not mix the components of any lifter. Service kits of component parts are available for both types of lifters.

Servicing Hydraulic Lifters—Failure of a hydraulic lifter is generally caused by an inadequate oil supply, dirt or other foreign substance. An air leak at the intake side of the oil pump or too much oil in the engine will cause air bubbles in the oil supply to the lifters, causing them to collapse. This is a probable cause of trouble if several lifters fail to function, but air in the oil is an unlikely cause of failure of a single unit.

In servicing the lifters particular attention should be given the plunger and valve. The plunger should be checked for signs of scoring or wear, and the valve for pitting. Check the valve seat in the end of the plunger for any condition that would not allow the valve to seat perfectly. If any of the above conditions are apparent, install a new lifter assembly.

Do not disassemble a lifter in dirty surroundings or on a dirty work bench. Use clean paper on the bench and, after the lifter has been disassembled, place the loose parts in a numbered rack with the parts of each unit together. Then submerge in clean kerosene as a protection against dirt or corrosion.

With more than one lifter disassembled it is imperative to keep the parts of each lifter separate. The plunger and valve must always be fitted in the same body.

Disassemble Lifter—With a suitable tool, pry out the plunger retainer ring. Clean varnish deposits from inside the lifter body above the push rod seat. Then invert the lifter body and drop out the parts.

Cleaning Lifters—Wash all lifters in a suitable solvent that will remove all trace of varnish and carbon (paint thinner will do). Then, working on one lifter at a time and using clean lint-free cloths, thoroughly wipe off all parts. Clean the plunger and the internal and external surfaces of the body with a hard wiping action to remove any varnish residue.

To insure absolute cleanliness of a reconditioned lifter assembly, it is advisable to service one at a time, assembling it before working on the next one.

Fig. 19 Hydraulic valve lifters. V-266, 304, 345

Fig. 20 Tappet and guide construction. RD engines

Fig. 21 Valve timing on 6-cylinder engines

Inspection—Inspect the lifter body for blow holes and scoring. Replace entire unit if body is roughly scored or grooved.

Using a magnifying glass, inspect the check valve seat for defects. Inspect the outer surface of the plunger for scratches or scores. Defects in the check valve seat or scores or scratches on the outer surface of the plunger which can be felt with the fingernail are causes for replacing the entire unit.

Replace the push rod seat if the area where the push rod contacts is rough or otherwise damaged.

Using a magnifying glass, carefully examine the check valve for nicks, imbedded material or other defects which would prevent proper seating. Even though no defects are found it is advisable to discard the old valve and use a new one when servicing a lifter.

Assembling Lifters—Rinse all parts in clean kerosene and assemble without drying. This will avoid the adherence of dust or lint if they are blown off or wiped with cloth.

Place the parts in the body in the following order: spring, valve and plunger. The plunger must slide freely in the body. Place the push rod seat on the plunger and depress these parts and install the plunger retainer in the groove in the body.

A-55, BD and SD Engines

Valve lifters or tappets are of the barrel type, operating in guide holes bored in the cylinder block. The lifters can be lifted out of the block after taking off the engine side cover and removing the push rods.

RD Engines

These lifters are of the mushroom type operating in guide holes bored in the cylinder block. To remove lifters, therefore, it is necessary to take out the camshaft and remove the lifters through the bottom of the engine.

The valve lifter bores have spring-loaded retainers in the block, Fig. 20, which are used to hold up the lifters when pulling out the camshaft. When the lifter is pushed up the retainer snaps into the groove at the top of the lifter. After the camshaft is installed, the lifters may be pushed down into position by the push rods.

TIMING GEARS OR CHAIN

When valves are correctly timed, the timing marks on the gears or sprockets should be adjacent to each other. Fig. 21 illustrates the gears on 6-cylinder engines. A chain is used only on A-55 engines.

CAMSHAFT & BEARINGS

All Engines

Camshaft bearings should be installed in sets and care must be exercised to see that the oil holes in the bearings and the oil feed holes in the block are aligned to assure adequate lubrication.

Fig. 21A Checking clearance between valve lifters and camshaft bearings. 4-152 engine

4-152 Service Note

Camshaft bushings must be installed so as to provide running clearance between valve lifters and bushings as shown in Fig. 21A.

PISTONS & RODS, REMOVE

All Engines

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals.

Make sure rods and pistons are properly numbered so they can be reinstalled in their proper cylinders. It is advisable to install the caps on the rods to avoid mixing parts.

Fig. 22 Correct assembly of pistons and rods. V8 engines

PISTONS & RODS, ASSEMBLE

V8 Engines

For correct assembly of the connecting rod to the piston, the rod bearing tangs will be toward the domed side of the piston (marked "up") for proper installation, Fig. 22. This is important in that the rod and piston must be assembled correctly so that when the piston is installed in the engine the chamfered side of each rod is located against the crankshaft face. The chamfer provides clearance at the crankshaft fillet.

Place the piston in a piston vise, and with the piston heated to approximately 200°, in a piston heater or boiling water, position the rod in the piston and install the piston pin.

A-55 and 6-Cyl. Engines

On A-55, BD and SD engines, assemble the piston to the rod so that the vertical slot in the piston skirt is on the same side as the numbered side of the rod. And when installed in the engine, the slotted side of the piston is on the camshaft side of the engine.

On RD engines, the step on the piston head must be installed in the cylinder on the side opposite to the camshaft.

4-152 Engine

For correct assembly of the connecting rod to the piston, the rod bearing locators (bearing tangs) must be toward the dome side (marked "up") of the piston. And when installed in the cylinder, the word "up" on the piston goes toward the top (camshaft) side of the engine.

PISTONS, REPLACE

All Engines

When fitting a piston, wipe the cylinder wall clean with a cloth and insert the piston upside down in the bore (rings and pin removed). Use a ½″ wide feeler gauge which is long enough to extend the full length of the piston. The thickness of the feeler should be the same as the piston clearance given in the chart.

With the feeler hooked to a spring scale it should require the number of pounds given in the following table to withdraw the feeler gauge from between the piston and cylinder:

Engine	Lbs. Pull	Desired
4-152	3 to 7	5
V-266, 304, 345	3 to 7	5
V-401, 461, 549	10 to 14	12
BD	6 to 18	12
RD	6 to 18	12
SD	6 to 18	12

NOTE—When steel-band-in-skirt pistons are used, the tolerances are held much closer than for other types. Furthermore, the feeler gauge method of checking this clearance is not practical. To attain proper fitting use micrometers for making piston selection and then check clearance as follows:

1. Wipe both piston and cylinder wall with clean, dry cloth.
2. Install piston top downward into cylinder.
3. A non-knurlized piston should be fitted so that there is .0008″ to .0013″ running clearance. This clearance will permit the piston to fall slowly through the cylinder bore of its own weight.

Fig. 23 Removing dry type cylinder sleeve

Fig. 24 Installing dry type cylinder sleeve

4. Knurlized pistons should fit slightly closer. These pistons are fitted so there is a slight drag (1 to 2 lbs.) to a light push fit in the cylinder bore.

PISTON RINGS, REPLACE

All Engines

Always use standard size rings in cylinder bores that are standard at the bottom, regardless of the amout of taper in the bore. Oversizes must be determined by the measurement of the narrowest portion of the bore.

New rings should be fitted according to the instructions furnished with the ring package. Ring grooves must be clean and free from carbon and must show no perceptible wear.

PISTON PINS, REPLACE

4-152 Engine

Piston pins are a press fit in the connecting rod. The fit should be .0006-.0012″ in the rod and .0005-.0009″ loose in the piston.

A-55 Engine

Piston pins should be a hand push fit in the piston. The fit can be checked after the rod has been assembled to the piston by holding the piston with rod in a horizontal position. The weight of the large end of the rod should not be quite enough to turn the pin in the piston. Do not ream out piston pin bosses since oversize pins are neither supplied nor permitted.

V-266, 304, 341

Piston pins are a press fit in the connecting rod. The fit should be .0002-.0009″ tight in the rod and .0003-.0007″ loose in the piston.

V-401, 461, 549 & 6-Cyl.

Piston pins are of the floating type, being free to rotate in both the rod and piston bosses. Snap rings, located in grooves in the piston bosses, prevent the pins from rubbing against the cylinder walls.

Select pins that can be installed by pushing with the palm of the hand with piston heated.

CYLINDER SLEEVES

BD-269, RD-372, 406, 450

This type sleeve is removed and installed as shown in Figs. 23 and 24.

These sleeves may be rehoned to take .005 and .010″ oversize pistons. If necessary to exceed .010″ oversize, a new sleeve and piston should be installed.

To remove a sleeve of this type, use screw with pressure plate and sleeve as shown in Fig. 23. Make sure the shoe is square under the sleeve and that the entire assembly is centered on the sleeve to be removed. Tighten the nut to pull the sleeve out of the block. Note the size marked on the outside of the sleeve and replace with the same size.

Before installing the new sleeve, thoroughly clean the bore of the block as well as the outside of the sleeve, especially under the top flange. Then coat the outside of the sleeve with a light mixture of white lead and oil to facilitate installation.

Place the sleeve in the bore and pass the shoe and screw down through the sleeve, bringing the shoe to rest against the wall of the cylinder bore, Fig. 24. Turn the shoe on an angle to obtain maximum bearing. Place the pressure plate squarely on top of the sleeve and turn the nut down to the plate.

Start the sleeve into the bore by hand pressure on the nut. Then after the sleeve is started into the bore, turn the nut with a ratchet, continuing with care until the sleeve is almost in its final position. Release the nut slightly and check to see that the shoe has not slipped and is still well supported on the cylinder boss. See that the flange is clean and then tighten the nut to draw the sleeve into its final position.

After installing the sleeve, it should be honed to remove any distortion and to size it properly for the piston to be used.

ROD BEARINGS, REPLACE

All Engines

These bearings are of the precision insert type, requiring no scraping or reaming.

When installing bearings, be sure the back of the bearing shells as well as the bearing seats in the rods are smooth and clean.

Bearing clearance may be checked with Plastigage, which is available at any auto parts jobber. Instructions for its use are furnished with the package.

Lacking Plastigage, however, use a piece of tough paper or shim stock ¾″ square which measures about .0005″ under the maximum allowable bearing clearance. Oil the shim on both sides and lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap bolts to normal tension.

The clearance is correct if the rod can be moved endwise when tapped lightly with a hammer. If the rod can be moved endwise by hand, clearance is too great. On the other hand, if the rod will not move when tapped lightly with a hammer, not enough clearance is present.

When using a torque wrench tighten bearing caps to the torque loads given in the table.

MAIN BEARINGS, REPLACE

All Engines

These bearings are of the insert type, requiring no reaming or scraping. They may be removed and replaced without removing the crankshaft.

Plastigage may be used to check bearing clearances, and instructions for its use are furnished with the package.

Lacking Plastigage, an alternate method is to use a piece of tough paper or shim stock 1″ square which measures about .001″ under the maximum allowable bearing clearance. Oil the shim on both sides and lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap bolts to normal tension.

Rotate the crankshaft through a two-inch arc (one each way) and if it is movable with a fairly heavy drag, the clearance is correct. If there is no perceptible drag, the clearance is too great. On the other hand, if the shaft cannot be moved, not enough clearance is present.

Be sure that the bearings are smooth and clean on both sides when installed. This applies to the bearing seats as well.

When using a torque wrench, tighten bearing caps to the torque loads given in the table.

CRANKSHAFT OIL SEAL, REPLACE

4-152 Engine

The rear main bearing oil seal can be replaced with the engine in the chassis by first removing the transmission, clutch and flywheel.

V8's and 6-Cyl.

Crankshaft rear bearing oil seal consists of two pieces of special packing. One piece is installed in the groove in the rear bearing cap and the other piece is installed in a similar groove in the cylinder block.

Position the rear bearing seal in the groove in the cylinder block. Lay an improvised mandrel in the bearing bore and strike the mandrel with a hammer to drive the seal into the groove. Install the seal in the bearing cap in a similar manner. Using a sharp knife, cut off both ends of each seal which project out of the grooves. When cutting off the ends of the seals, do not leave frayed ends which would prevent proper seating of the bearing cap if the ends should extend between cap and cylinder block.

OIL PUMP REPAIRS

A-55 Engine

To service the oil pump, take off the cover and tilt the pump body to take out the rotors.

Replace pump drive shaft and gear if gear teeth are chipped or worn. Make sure pump drive shaft oil passage is clear. If either outer or inner rotors are worn, both rotors as well as pump shaft must be replaced.

When reassembling note that chamfered edge of outer rotor is installed with chamfer toward base of body and away from cover. To assemble otherwise will result in pump seizure when cover is tightened down.

4-152, V8's and 6-Cyl.

Conventional gear type oil pumps, located in the crankcase, are used on all engines. After removing the oil pan, the

pump may be unfastened from its mounting and disassembled for repairs.

Inspect the pump gears for nicks or burrs. Inspect the bottom cover for wear and dress down on a surface plate with emery if necessary. Place the bottom cover on the pump and check the drive shaft end play. If end play is excessive (more than .006"), replace the drive and idler gears.

Service Note

Whenever the oil pump is removed, the distributor will have to be taken off as well in order to reinstall the pump without damage. The reason for this is that the slots in the end of the oil pump drive shafts must match the tangs on the end of the distributor drive shaft. If an attempt is made to install the pump while the distributor is in place, it will be difficult or impossible to align the slots and tangs with the result that the pump will be damaged when its mounting bolts are tightened. Be sure to retime the ignition when the oil pump and distributor are installed.

Fig. 25 Sectional view of RD engine water pump. Pumps used on V8 and BD engines are similar

WATER PUMP REPAIRS

V-401, 461, 549, BD, RD

Fig. 25 shows the pump used on RD engines. The same design is used on BD engines except that provision is made for only one fan belt. To overhaul the pump, proceed as follows:

Remove the fan pulley, being careful not to damage its flanges. Release the snap ring from the front bearing. Take off the rear cover plate. Press the shaft out of the impeller from the rear and remove the shaft and bearings as a unit. Press the shaft from the bearings, sleeve and slinger, and remove the lock rings. Release the lock ring from the impeller and take out the seal washer, seal and spring, noting carefully the arrangement of these parts so that no difficulty will be experienced when assembling.

Before assembling the pump, check the thrust face of the housing. If the surface is not smooth or true it should be smoothed up with a special water pump facing cutter.

To assemble the pump, apply a liberal amount of grease to the bearings and to the shaft between the bearings. Then install the shaft and bearings in the housing as a unit. Press the impeller and seal assembly down onto the shaft, pressing it down just flush with the end of the shaft. Complete the assembly by installing the cover plate and fan pulley.

4-152, V-266, 304, 345, A-55, SD

The pumps used on these engines are of the sealed ball bearing type packed with lubricant at the time of assembly and requiring no further lubrication. When disassembling, carefully note the arrangement of the seal parts so that correct assembly may be assured.

Never soak the shaft and bearing assembly in cleaning solvent because it will dissolve the lubricant. To clean the shaft and bearing, merely moisten a cloth with cleaning fluid and wipe away any surplus lubricant or other foreign matter.

Be sure the face of the housing against which the thrust washer turns is smooth and true. If not, smooth it up with a special water pump facing cutter.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

Service Note

On V-266, 304 and 345 engines, connect timing light to No. 8 spark plug.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake

needle and seats may be checked under pressure if the fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading on carburetors with automatic choke may be due in many instances to sluggish choke valve opening during cold drive-away, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Automatic Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Fig.④ —Dashpot used with automatic transmission. Make sure choke valve is wide open when making this adjustment.

⑤—Loosen jam nut and rotate complete dashpot to obtain clearance listed.

⑥—Set throttle stop screw so it just touches fast idle cam at curb idle. Make this setting before adjusting idle mixture screws.

⑦—Adjust fast idle stud so there is the clearance listed between stud and fast idle cam when throttle valves are set for curb idle and choke valve fully open. Make this setting before adjusting idle mixture screws.

⑧—This is a fuel level setting. With engine running, remove sight plug from side of bowl. If fuel level is not on a line with threads at bottom of sight hole, loosen lock nut slightly (top of bowl) and turn adjusting nut as required. Turn nut clockwise to lower fuel level and vice-versa.

CENTURY LPG

RD-501, V-304, V-345, V-401, 461, 549

Idle fuel adjustment automatically gives the correct economy mixture for both full and part throttle operation. This is accomplished by the use of a connecting drag link which causes the throttle plate and metering valve to operate simultaneously. The idle fuel adjustment is made through an adjusting screw found in each end of the drag link. Either end may be used to make the adjustment. Setting the idle fuel mixture as given in the following steps will synchronize the throttle plate and the metering valve to give the correct mixture.

1. Set throttle fast idle by turning throttle stop screw in from closed throttle position 3 or 4 turns.
2. Start engine.
3. Adjust idle adjusting screw in drag link until engine runs smooth. Turn screw clockwise to enrich the mixture.
4. Turn throttle stop screw out until engine idles at 600 rpm.
5. Readjust idle adjusting screw in drag link to get highest possible engine rpm. Should it go higher than 900 rpm, readjust throttle stop screw to obtain 600 rpm. Then readjust idle screw in drag link to obtain highest engine rpm.
6. Adjust engine to 400 rpm idle by throttle stop screw.
7. Replace cotter pin in drag link to lock adjustment screw.

ENSIGN LPG, MODEL R

Carburetor Starting Adjusting Screw, Adjust

Loosen the lock nut on the starting adjusting screw and turn clockwise until it bottoms. Then turn the screw counterclockwise the required number of turns and tighten lock nut. The number of turns required for the various engines is as follows:

BD-240	5/8
BD-264	7/8
BD-282	3
BD-308	2
RD-372	2
RD-406	1
RD-450	2

Regulator Unit Idle Adjusting Screw, Adjust

Turn the idle adjusting screw on the regulator unit clockwise until it bottoms gently. Then turn the screw counterclockwise the required number of turns as follows:

BD-240	7/8
BD-264	5/8
BD-282	3/4
BD-308	1
RD-372	3/4
RD-406	2
RD-450	1 1/4

Economizer Load Adjustment, BD Engines

Loosen large lock nut and turn load adjusting screw clockwise to its extreme position. Then turn screw counterclockwise the required number of turns (see below) and tighten lock nut.

BD-240	5
BD-264	7
BD-282	4 3/4
BD-308	9 1/2

Economizer Load Adjustment, RD Engines

With engine not running, disconnect vacuum line from economizer. Then set the load adjustment as follows: Loosen large lock nut and turn entire economizer clockwise until body assembly bottoms in carburetor. Then turn body assembly counterclockwise the number of turns given below. Temporarily plug loose end of vacuum line. Start engine and, when at operating temperature, set hand throttle to approximately 2/3 of governed speed. Turn economizer assembly clockwise until engine speed drops slightly. Note economizer position. Then turn economizer clockwise until engine speed picks up again and again drops slightly. Note position of economizer assembly and then turn counterclockwise to mid-point between this and previous position. Tighten lock nut. It is necessary that the load adjustment be set correctly before further connections or adjustments are made.

RD-372	4 3/8
RD-406	5
RD-450	4 3/4

Economizer Part Throttle Adjustment, RD Engines

Loosen small lock nut on economizer cover and turn economizer adjusting screw counterclockwise to its extreme position. Then turn screw clockwise the required number of turns (given below) and tighten lock nut. Unplug vacuum line and reconnect.

RD-372	4 1/2
RD-406	4 11/16
RD-450	3 3/4

Clutch Section

HYDRAULIC CLUTCH CONTROL

Used with 13", 14", 15" Clutches; on 1600-1890 Models and CM-80 and CM-110 Models

As shown in Fig. 1, the system consists of a pedal-operated cylinder, similar to a brake master cylinder, which transmits hydraulic fluid to the slave cylinder mounted on the transmission. The slave cylinder moves the clutch release bearing to engage and disengage the clutch. Tubing and flexible hose connect the two units.

The hydraulic cylinder is filled with high grade hydraulic brake fluid. To replenish fluid, fill the reservoir to within 3/4" from the top of the filler neck.

Bleeding System

Any air trapped inside the system will eventually bleed itself to the reservoir. However, this is not accomplished immediately and takes place over an extended period of clutch pedal operation. For this reason a bleeding operation should be performed whenever the units have been disassembled or fluid lines disconnected. The bleeding procedure is accomplished in the same manner as for hydraulic brake systems. The bleeder screw is located on the lower end of the slave cylinder.

Adjustments

Two adjustments affect clutch operation and must be checked each time the hydraulic clutch is serviced. The first of these is clutch pedal stroke adjustment which is made at the hydraulic cylinder piston and push rod. The second adjustment is for clutch release bearing clearance. This adjustment is made at the upper end of the slave cylinder.

Clutch Pedal, Adjust Except 1600-1890 Models

1. With clutch pedal disconnected from hydraulic cylinder push rod, pull piston and push rod assembly its full length of stroke out of cylinder. *Be sure piston is held snugly against snap ring stop in end of cylinder.*
2. Hold clutch pedal up against pedal stop.
3. Adjust clevis yoke on end of piston push rod until yoke can be fastened to clutch pedal. Tighten jam nut on yoke. Install end pin and cotter pin.

1600-1890 Models

1. Measure clutch pedal height from lower edge of clutch pedal lever to toe boards. (measurement should be made at 90° to toe boards)
2. If pedal height is not 5 5/8", loosen lock nut on master cylinder push rod and adjust push rod to obtain proper pedal height.

Clutch Release Bearing Clearance Except CM-80, CM-110 and 1600-1890 Models

1. Remove slave cylinder push rod return spring, Fig. 2. Loosen clevis yoke lock nut on push rod. Remove cotter pin and clevis yoke end pin. Remove two hex head mounting bolts from slave cylinder body and move cylinder away from clutch re-

Fig. 1 Hydraulic clutch control. CM-80, CM-110 and 1600-1890 Models have suspended pedal

Fig. 2 Slave cylinder mounting details

Fig. 3 Clutch air-over-hydraulic power unit (Mini-Pak)

lease lever.

2. Move clutch release lever upward until release bearing contacts clutch release levers. With push rod in released position, turn clevis yoke until yoke hole indexes with clutch release lever hole when slave cylinder mounting holes are aligned with mounting bracket holes. *Be certain that clutch release bearing is held against release levers while completing this step.*
3. After completing Step 2, turn clevis yoke on to push rod 2½ turns which provides approximately ⅛″ clutch release bearing-to-levers clearance. Tighten lock nut on push rod to keep clevis yoke from turning while reinstalling slave cylinder.
4. Reinstall slave cylinder. Connect clevis yoke and clutch release lever with end pin. Insert cotter pin. Recheck lock nut on push rod and install push rod return spring, keeping spring clips aligned.

CM-80 and CM-110

This adjustment should follow clutch pedal adjustment.

1. Depress clutch pedal until there is the feel of the release bearing contacting the clutch release levers.
2. Adjust the pedal free movement by loosening the lock nut on the slave cylinder and turning the push rod to obtain 1½″ pedal free movement.
3. Tighten lock nut and recheck pedal free movement.

1600-1890 Models

This adjustment should follow clutch pedal adjustment.

1. Loosen lock nut on clutch slave cylinder push rod. Remove cotter pin and yoke pin.
2. Move clutch release lever forward until release bearing contacts clutch release fingers. With slave cylinder push rod assembly retained in the released position (bottomed), turn yoke until yoke hole indexes with clutch release lever hole. Install yoke pin.
3. After completing step 2, remove yoke pin and shorten linkage by turning yoke 4 complete turns. Reassemble yoke pin and cotter pin and tighten lock n t on push rod assembly.

CLUTCH AIR-HYDRAULIC POWER UNIT

This unit, Fig. 3, is a clutch assistor consisting of a combined compressed air and hydraulic assembly used to supply power for clutch operation on vehicles equipped with a hydraulic clutch cylinder. Clutch actuation is obtained with low clutch pedal effort while retaining "drive feel" during clutch engagement. In the event of power failure, clutch actuation is made in the usual manner except that increased pedal effort is required by the driver. The assembly consists of the following basic components:

1. A compressed air cylinder containing an air pressure operated piston and push rod.
2. A hydraulic cylinder and piston.
3. An air pressure control valve containing a hydraulic pressure operated piston, an air pressure poppet, an atmospheric pressure poppet valve and an air pressure control diaphragm.

Operation

To disengage the clutch, the clutch pedal is depressed which forces fluid out of the clutch hydraulic cylinder under pressure into the clutch assistor hydraulic cylinder and control valve piston chamber, Fig. 4. When fluid pressure acting upon the control hydraulic piston reaches a pre-determined value, the valve poppet closes the atmospheric port and opens the air pressure port. This action admits compressed air to the air pressure side of the air cylinder, Fig. 5. The force from the air pressure applied to the air piston is transmitted through the push rod to the hydraulic piston of the clutch assistor and through the clutch push rod to the clutch release lever to disengage the clutch.

To engage the clutch, the driver gradually releases the foot pressure on the clutch pedal. As pressure is reduced in the clutch assistor hydraulic cylinder, pressure will also be reduced in the clutch assistor hydraulic cylinder and control valve chamber. The air pressure applied to the air pressure piston will also be reduced. Fluid is then returned from the clutch assistor hydraulic cylinder in accordance with release of air pressure. When foot pressure on the clutch pedal is released sufficiently to allow the control valve to close the air pressure port and reopen the atmospheric port of the clutch assistor, the clutch is fully engaged.

Adjustment

The free pedal travel will be slight (approximately ¼″) and can be compared to the free travel that is acceptable for the pedal of hydraulic brake systems. The clutch assistor should be adjusted to provide complete engaging and disengaging of the clutch when the pedal is depressed and released. An average of ½″ clutch release bearing travel should be provided for proper release of the clutch. The stroke of the clutch assistor hydraulic cylinder should be approximately $1\frac{13}{16}$″.

Repairs

When overhauling the clutch assistor, refer to Fig. 6 as a guide. Be very careful when handling hydraulic system parts to prevent their coming in contact with mineral oils or grease. *Do not handle hydraulic piston cups or seals with greasy hands.* When overhauling the clutch assistor, always use a repair kit and install all the parts contained in the kit regardless of the condition of the old parts. If replacement of the air cylinder leather piston packing is necessary, use a piston packing kit in addition to the repair kit.

Lubrication

Do not lubricate the clutch assistor until it has been permanently installed on the vehicle. This is a safeguard against lubricating oil entering the hydraulic section which might cause damage to the rubber cups and seals. The clutch assistor should be lubricated every 10,000 miles or every six months, whichever occurs first, with vacuum cylinder oil.

To lubricate, remove the ⅛″ pipe plug located in the end of the air cylinder shell and inject vacuum cylinder oil through this port until oil begins to run out, then replace pipe plug. *During lubrication, the engine should be shut off and the clutch assistor should be in the released position.*

SINGLE PLATE CLUTCHES

Removal

When removing the transmission for the purpose of gaining access to the clutch or for any other reason, extreme care should be taken to support the weight of the transmission until it is completely removed so that the main drive gear splines will clear the driven member. The reason for this is that there is the possibility of distorting the driven member which will prevent a free release of the clutch.

The 10-TT and 15-TT pressure plates are drilled and tapped so that three capscrews and washers may be inserted through the back plate to hold the clutch assembly compressed during removal.

The 11-RT, 12-RT, 13-RT and 14-RT clutches are held in a compressed position with retaining clips in place of retaining capscrews. Place a retaining clip between the back plate and pressure plate lug and loosen the back plate-to-flywheel capscrews only enough to wedge the clip in place. Turn the flywheel one-third turn and install a second clip in the same manner. Follow the same procedure for the third retaining clip. All capscrews should be backed out gradually to avoid damage to the back plate.

Install Clutch to Flywheel

Position the driven member and clutch pressure plate assembly on the flywheel, using a stub shaft to align the driven member. On RT Series clutches, install the clutch-to-flywheel retaining capscrews and tighten only to a point where the retaining clip can be removed. Turn the flywheel one-third turn and remove the remaining clips in the same manner. Tighten all retaining capscrews securely and remove the stub shaft.

The 10-TT and 15-TT clutches are installed in the same manner; however, the retaining capscrews (in place of clips) can be removed after installation is completed.

Lubrication

Easy clutch operation is dependent to a large degree on lubrication of the clutch release shaft and clutch control linkage, and the application of a thin coating of lubricant to the wearing surfaces of the clutch release sleeve.

Use a low pressure hand gun and lubricate the clutch release sleeve every 15,000 to 20,000 miles under normal conditions. For unusual "stop and go" con-

Fig. 4 Schematic diagram of typical air-hydraulic power unit

Fig. 5 Sectional view of air-hydraulic power unit

Fig. 6 Exploded view of air-hydraulic power unit

ditions, lubricate every 10,000 miles. Use lubricant similar to Lubriplate No. 110. Do not overlubricate.

Clutch Pedal, Adjust

Suspended Pedal Type—The clutch pedal should have a minimum of 2″ free movement before clutch pressure is felt. Increase or decrease clutch pedal free travel by loosening the rod lock nuts on each side of the turnbuckle. Looking down on turnbuckle, turn it counterclockwise to increase free travel or clockwise to decrease free travel. Tighten lock nuts after adjustment.

Conventional Pedal—If there is less than 2″ of free movement of the pedal, adjust the yoke on the clutch release rod as required to obtain at least 2″ of free pedal travel.

TWO PLATE CLUTCHES

This clutch, Fig. 7, is a two-plate dry disc type with the two driven plates mounted on the splined clutch shaft. The driving disc, which separates these two plates, is mounted within the flywheel on four pins. As an aid to gear shifting a clutch brake is provided, which comes into action when the clutch pedal is fully released.

Clutch Removal

When removing the transmission to gain access to the clutch or for any other reason, extreme care should be taken to support the weight of the transmission until it is completely removed and the main drive gear splines clear the driven members. Failure to do so may distort the driven members which will prevent a free release of the clutch.

Place two ¾″ spacer blocks of wood between clutch release bearing and spring plate hub. Disengage the clutch with the clutch pedal for installation of the spacer blocks.

Remove hex bolts and washers holding flywheel ring gear to flywheel and lift off clutch assembly and rear driven disc. Remove driving disc and pins from inside of flywheel and remove front driven disc.

Assemble Clutch to Flywheel

1. Check flywheel pilot bearing to make sure it is free.
2. Install front driven disc in flywheel with riveted hub flange toward transmission. This is the disc on which the hub protrudes nearly equal on each side of the disc.
3. Place four square-headed driving pins in flywheel and make sure they are square with flywheel face. Place driving disc in flywheel and index with driving pins.
4. Install rear driven disc with longest hub toward transmission.
5. Place clutch assembly in flywheel and line up driven disc splines with pilot bearing, using a main drive gear shaft or aligning bar.
6. Secure clutch to flywheel and tighten hex bolts around flywheel ring uniformly so as not to stress flywheel ring.
7. Remove two wooden spacer blocks and aligning bar.

Fig. 7 Two-plate clutch

Assemble Transmission to Engine

1. Make sure two brake discs and brake washer are on main drive gear of transmission.
2. Turn clutch release yoke so top is back toward transmission and turn clutch release bearing with flat part on top.
3. Raise transmission up square with engine and slide splined main drive gear through release sleeve and driven discs. Turn release yoke fingers down over clutch release bearing and index release fingers and bearing.

Adjustments

Whenever the clutch is rebuilt, and periodically when free pedal travel is reduced, there are two adjustments which must be made. The first of these is the internal clutch adjustment and the second is the external or pedal and control linkage adjustment. *The internal adjustment must always be made first.*

Internal Adjustment—This adjustment is checked by removing inspection cover from clutch housing and measuring the clearance or gap between the clutch release bearing and clutch brake, and also between release bearing and spring plate hub. Dimensions at each place should be ½″ (plus or minus $\frac{1}{32}$″), Fig. 7.

1. Rotate engine flywheel until adjusting ring lock plate is exposed and remove lock plate.
2. Release clutch by blocking clutch pedal down in depressed position.
3. Use a pry bar to turn adjusting ring. Turn ring counterclockwise to move release bearing toward flywheel or clockwise to move bearing away from flywheel. Rotation or movement of one lug will move release bearing housing approximately $\frac{1}{32}$″.
4. Release clutch pedal. Recheck clearance. After adjustment is correct, install adjusting ring lock plate.

External (Pedal) Adjustment—This adjustment depends on the type of clutch control system used on the truck. The clutch release bearing may be actuated by mechanical, hydraulic or a combination of air-hydraulic means.

In general, the mechanically controlled clutch should have 2″ of free pedal travel before the clutch starts to disengage. Pedal should be checked occasionally and adjusted whenever free travel has been reduced to less than 1½″.

If equipped with hydraulic or air-hydraulic controls, adjust pedal as outlined previously.

Manual Shift Transmission Section

For Clark, Fuller, New Process, Spicer and Warner transmissions used in International trucks, see the "name" chapter for service procedures

MODELS T1, T2

Disassemble, Figs. 1, 2

1. Take off control cover.
2. Remove universal flange nut and pull off flange.
3. Remove speedometer driven gear and front and rear bearing retainers.
4. Drive countershaft out rearward, allowing cluster gear to lie in case.
5. Pull main drive gear out through front.
6. Remove mainshaft front pilot bearing and push mainshaft far enough to rear to permit removal of speedometer drive gear and rear bearing.
7. Lift mainshaft and gears out through top.
8. Lift out cluster gear and washers.
9. Drive reverse idler shaft out through rear and lift out gear.
10. To disassemble mainshaft, slide the low and reverse sliding gear and synchronizer unit from the shaft. Release snap ring and take off the second speed gear, bushing and thrust washer.
11. Reverse the order of the above procedure to assemble the transmission.

T2 O. D. TRANS.

Disassemble, Fig. 3

1. Drain lubricant.
2. Remove companion flange.
3. Remove lockout switch.
4. Remove governor.
5. Drive out tapered pin (from underside) which holds overdrive control shaft in case. Pull shaft with lever from case.
6. Remove screws which attach overdrive case and adapter to transmission. Tap end of output shaft lightly with a soft mallet and remove overdrive case. This prevents shaft and ring gear from being removed with case and spilling the 12 clutch rollers.
7. With case removed, slide governor and speedometer drive gear from shaft.

8. Reinstall one capscrew to hold adapter to transmission.
9. Remove shift rail adapter spring from inside of overdrive case. Pry out control shaft and ouput shaft oil seal from case. Discard seals and replace with new ones upon reassembly.
10. Remove outer snap ring, rear bearing and inner snap ring from shaft.
11. Remove output shaft and ring gear, catching 12 clutch rollers, Fig. 4.
12. Separate ring gear and output shaft by removing large snap ring.
13. Pry retaining clip that retains roller clutch assembly (free wheeling unit) to output shaft. Then remove free wheeling cam and pinion case assembly, Fig. 5. Remove retaining clip holding the two units together and separate.
14. Slide sun gear with shifting collar off end of transmission mainshaft and at the same time remove shift rail from case adapter, Fig. 6.
15. Remove two snap rings which retain shifting collar to sun gear and separate collar and gear.
16. Remove "C" washer located on shift rail between shift fork and "C" washer cup. Then slide fork, "C" washer cup and reverse lock-up spring from shift rail.
17. Unfasten solenoid from case and turn clockwise ¼ turn and remove from adapter.
18. Remove large snap ring located in adapter next to retainer plate with oil trough. These parts can then be removed as shown in Fig. 7.
19. Before further disassembly of the overdrive unit can be made, it will be necessary to partially disassemble the transmission as follows:
20. Remove transmission cover.
21. Remove main drive gear bearing retainer, noting that oil drain is located below.
22. Start main drive gear bearing out of case by tapping on outer race from inside of case. As soon as bearing is started, work it out of case by moving end of shaft from side to side.
23. Pull overdrive adapter and mainshaft toward rear of transmission case, lowering extended end of mainshaft to permit removal of synchronizer from inside of case. Remove snap ring and strip mainshaft of parts.
24. Remove large snap ring holding bearing in adapter. Pull adapter off bearing and press bearing from mainshaft.
25. Turn transmission low and reverse shift lever shaft to its forward limits. This will provide clearance for removal of reverse lockout cam.

Assemble

1. Reverse the disassembly procedure to assemble the transmission and overdrive, observing the following precautions:
2. Prior to assembling the overdrive unit, select correct thickness of snap ring that will secure (a) mainshaft

Fig. 1 Three speed transmission. Model T-1

Fig. 2 On T1 and T2 transmissions the synchronizer consists of the parts shown plus the synchronizer clutch gear which is secured to the mainshaft with a snap ring

rear bearing in overdrive case adapter (b) rear bearing to mainshaft, (c) retaining plate with oil trough in adapter, and (d) output shaft bearing in overdrive case with no perceptible end play.

3. Always install new gaskets and oil seals if unit has accumulated any extensive mileage or if damaged in removal.
4. When installing sun gear control plate and blocker ring assembly, *be sure* that the blocker ring and pawl are properly positioned. Position blocker ring so that pawl will be located between the two lugs of the blocker ring. The notched side of the pawl should be positioned so that the notch faces toward top of transmission.
5. The solenoid should be installed so that opening in end of solenoid is located **to** the bottom and that plunger is engaged and locked in pawl.
6. To facilitate installing output shaft and ring gear, apply heavy grease to roller clutch cage to hold the 12 rollers in position. Then, with low gear of transmission engaged, turn cage and rollers counter-clockwise until the rollers are in their low positions on cam. Install output shaft and ring gear on pinion cage and roller clutch (free wheeling unit), turning the shaft to the left as the outer race encloses the rollers.
7. Prior to installing overdrive case to adapter, position shift rail retractor spring in case. Insert a pilot in case through retractor spring to assure spring alignment. While installing case, guide shift rail through retracting spring. Pilot will be forced from case. *Be sure* slotted portion in shift rail is properly positioned to take overdrive control shaft before installing case.

MODEL T-12

During the assembly of the transmission, lubricate all bearings, bushings, splines, shafts, selector poppet balls and springs, and the selector shift forks at their contact surfaces in the gear grooves with SAE 30 straight mineral oil. This is important to avoid possible damage when the reassembled transmission is placed into operation.

Assemble Mainshaft, Fig. 8

1. Position rear thrust washer on front end of center splines with its ground face to the front.
2. Slide on longer (2nd gear) brass bushing up to thrust washer with its engaging tangs toward front. *This bushing must be positioned so its oil hole is in line with the oil hole in the mainshaft, and so that the cutaway portion of the 3rd gear splined bushing will be over the synchronizer ball and spring when the tangs of the two bushings are engaged with the bushing lock ring.*
3. Position 2nd gear spacer and gear onto bushing with spur teeth of gear toward rear.
4. Slide on bushing lock ring and 3rd

①—Code number is listed on Vehicle Inspection Card attached to left sun visor.
②—See the Stock Transmissions Chapter for repairs on this unit.
③—Roadranger transmission.
④—Select-O-Matic transmission.
⑤—Includes torque converter.

gear bushing, locating the tangs of both bus ings in the lock ring.

5. Insert thrust washer pin spring into hole in shaft.
6. Position 3rd gear on bushing with cone toward front.
7. Slide on front thrust washer with machined face toward gear. While holding down pin with a thin punch through hole in gear cone, push thrust washer over pin. Turn washer to allow pin to engage one of the splines, Fig. 9. Check to see that gear end play is .003″ to .005″. Select and fit a thrust washer of the required thickness to establish this end play.
8. Fit three springs and poppet balls into front synchronizer unit and install 3rd and 4th sliding sleeve on synchronizer unit.
9. Insert 3rd and 4th gear spacer into synchronizer and slide unit onto mainshaft.
10. Install three springs and poppet balls in rear synchronizer and slide 1st speed gear on synchronizer unit.
11. Slide unit together with 2nd gear spacer onto splines of shaft.
12. Press mainshaft rear bearing into its housing and fit it to the shaft with the outer flange of the housing toward the rear.
13. Install speedometer drive gear spacer on mainshaft.
14. Insert speedometer drive gear key in mainshaft groove.
15. Install speedometer drive gear.
16. Install lockwasher and nut on mainshaft.

Assemble Countershaft

1. Insert snap ring into innermost groove in gear cluster.
2. Insert countershaft in vertical position in a vise with notched end down. Coat shaft lightly with chassis lube. Then position bearing ring over shaft and against vise jaws. Position needle rollers around shaft and install a second bearing ring.
3. Slide gear unit over shaft and bearing with large gear downward.
4. Remove shaft from vise, push bearing up against snap ring and secure in position with second snap ring.
5. Install outer needle roller bearing and retaining snap ring.
6. Slide countershaft bearing spacer into gear unit from rear end. Install rear needle roller bearing and secure with snap ring.
7. Temporarily install countershaft, cluster gear and thrust washers in case, using aligning tool as shown in Fig. 10. Then check end play of unit which should be .001″ to .003″. Select a rear thrust washer of the required thickness to establish this end play. Then remove shaft and thrust washers and allow gear unit to rest in bottom of case.

Assemble Main Drive Gear

1. Install bearing on main drive gear with its snap ring furthest from gear. Install lockwasher, tighten retaining nut and bend over locking tab.

2. Place main drive gear assembly into front of case, making sure snap ring rests against case.
3. Coat bore of main drive gear with chassis lube and install 18 needle bearings.

Assemble Transmission

1. Insert assembled mainshaft from rear. There is a dowel in rear bearing housing and this can be located with aid of gasket fitted between case and extension before housing is pressed into rear of case.
2. Press rear bearing housing into case, at the same time entering the mainshaft into the main drive gear pilot bearings.
3. Install countershaft through gear unit and thrust washers, using aligning tool shown in Fig. 10. Line up notched portion at front end of shaft with locating groove in front cover.
4. Insert 1st and 2nd speed shift with ball and spring held in position with aid of pilot bar, Fig. 11.
5. Insert 3rd and 4th shift fork with ball and spring also held in position with pilot bar.
6. Tap 3rd and 4th speed shift bar with

Fig. 3 T2 overdrive

Fig 4. Removing output shaft and ring gear

Fig. 5 Removing free wheeling shaft and pinion cage

Fig. 6 Removing sun gear and shift rail

Fig. 7 Removing retainer plate, pawl, and sun gear control plate

Fig. 8 Main drive line of T-12 transmission

Fig. 9 Installation of front thrust washer over locating pin on mainshaft. Model T-12

Fig. 10 Aligning tool used as pilot when installing countershaft. Make tool to dimensions shown. Model T-12

Fig. 11 Preloading shift fork ball and spring with pilot bar shown. Make pilot bar to dimensions shown. Model T-12

its slotted end toward rear of case, removing pilot bar.

7. Repeat same operation with 1st and 2nd speed shift fork and bar. This shaft has three grooves at its rear end.
8. Install reverse gear and shaft into case and secure shaft with set screw and lockwasher.
9. Install reverse gear shift fork, spring, ball and shift bar. This bar has two grooves at its rear end.
10. Position shift bar locating strip in rear of case.
11. Position speed change fork on speed change shaft and install lock pin, lockwasher and nut.
12. Position operating lever in speed change fork and install fulcrum pin. Tighten pin until lever is just snug between fork jaws and then back off 1/6 turn before securing pin with washer and nut. This lever should be free but without side movement. Position spacer washer over end of speed change shaft and install shaft into case.
13. Install inner lever on selector cross shaft and secure with taper pin. Position cross shaft with lever in case.
14. At the same time that shafts are placed in case, the change speed gate should be threaded over levers and entire assembly installed in case as a unit. The gate is located in position by its rounded ends in the machined recesses of side cover.
15. Install speedometer drive gear on mainshaft.
16. Install extension housing and new gasket on case.
17. Install side cover and new gasket.
18. Position new felt washers and oil seals to selector and speed change cross shaft.
19. Install main drive gear bearing shims and install front cover with new gasket, making sure bearing snap ring is held against transmission case.
20. Install clutch withdrawal lever, renewing the rubber dust cover if necessary.
21. Install selector shaft outer lever and secure with nut, washer and lock pin.
22. Install speed change shaft outer lever with nut, washer and lock pin.

Select-O-Matic Transmission Section

This unit, Fig. 1, consists of a torque converter and hydraulic clutch attached to a conventional five-speed transmission. The torque converter provides for the multiplication of the engine torque to give the best possible torque ratio for the various driving conditions encountered in starting, acceleration and high speed operation. The hydraulic clutch provides the break in the drive line between the torque converter and transmission to permit a change of gears in the transmission with the shift control lever. The torque converter dampens engagement forces when the clutch is reengaged, preventing shock loads as are experienced with typical direct dry clutch plates.

The hydraulic clutch is actuated by an electrical control button on the underside of the shift lever knob. Actuation of the button grounds the electrical circuit containing the solenoid valve, opens the valve and releases the oil pressure in the clutch assembly. This action frees the driven member, thereby releasing the drive line torque.

Transmission and Converter, Replace

1. Drain transmission and converter.
2. Remove gearshift lever, leaving control cover in place. After lever is removed, seal lever opening to prevent entry of dirt.
3. Disconnect solenoid control wire.
4. Disconnect propeller shaft at rear of transmission.
5. Support transmission on portable floor jack, making sure transmission is supported in alignment with torque converter. Then remove retaining bolts between converter housing and clutch housing.
6. Separate transmission from converter.
7. Remove clutch assembly, Fig. 2.
8. Support rear end of engine and remove engine rear mountings at converter housing.
9. Remove converter housing retaining bolts and remove pump and converter housing.
10. Through front of engine housing remove six bolts from converter drive plate. Then remove converter assembly.
11. Place converter on blocks of wood to prevent damage to pump drive tangs.

Converter Disassemble

1. Remove cover plate, noting location of thrust washer and seal ring.
2. Lift turbine from pump.
3. Remove reactor (stator), noting that the thick section of the blades are up.
4. Disassemble reactor unit. Remove bearing, clutch inner race and clutch assembly. Note that the reactor blade unit rotates in a clockwise direction when the clutch inner race is held stationary with the thick section of the reactor blades up.
5. The clutch, Fig. 3, has a flange on the front edge of the assembly. This flanged edge is located toward the front when placed in the reactor.

Inspection of Parts

Unless the units are free of dirt, operating difficulties might be expected since any dirt present in the assembly will circulate through the oil pump, solenoid valve, hydraulic clutch and torque converter. Transmission fluid is supplied to the entire unit from the common sump in the transmission.

During overhaul, all parts must be cleaned thoroughly and covered until ready for assembly. Do not use soiled rags or materials that will leave lint on the parts.

Do not use sealing compound on any internal parts. New "O" ring seals and gaskets should be installed any time the unit is disassembled.

When the converter hub is inserted into the collector ring and pump assembly, the seal ring should be heavily coated with grease to protect the lip of the pump seal as it passes over the seal ring. When the converter hub is withdrawn from the collector ring the lip of the seal will be damaged by the seal ring and for this reason must always be replaced.

Converter, Assemble

1. Place reactor on rear bearing.
2. Insert clutch in reactor unit with flange on clutch towards thicker section of blades, Fig. 3.
3. Insert inner race with turning motion in counterclockwise direction. Snap ring located in race must be up. Use wood blocks when tapping bearings in place.
4. Place reactor in pump. Note that reactor must rotate clockwise with reactor race held stationary.
5. Install turbine in pump.
6. Place new seals in cover plate.
7. Place thrust washer in cover plate, oil groove up. Use light coating of grease to hold washer in place.
8. Install cover plate on pump. Position drain holes in converter so they clear drive plate. Tighten bolts alternately across bolt circle to a torque of 15-18 lb. ft.

Pump, Disassemble

1. Remove solenoid and control valve from pump, Fig. 4. Use new seals when reassembling pump. Tighten bolts to a torque of 10-12 lb. ft.
2. Separate pump from collector ring.
3. Disassemble pump, Fig. 5.
4. The pressure regulator plunger parts are removed by extracting the roll pin from the pump housing. These parts can be removed for cleaning purposes, Fig. 6. The spring should be replaced if it does not measure 1.272". Examine the valve or plunger for wear or scored surface. Replace

Fig. 1 Sectional view of torque converter and hydraulic clutch attached to transmission

Fig. 2 Rear view of separated converter units

Fig. 3 Stator (or reactor) components

Fig. 4 Removing clutch control valve from collector ring. Note location of "O" ring seals

Fig. 5 Layout of pump parts

Fig. 6 Pressure regulator valve components

Fig. 7 Pressing bearing into reaction shaft. The dowel shown secures shaft to casting and is not to be removed

pump housing if valve is rough or in any way damaged. A scored plunger would indicate damage to the plunger bore in the pump housing. The O ring is installed on the spring seat or retainer.

Pump, Assemble

1. Press new pump seal to its seat in housing.
2. Install pressure regulator valve parts, Fig. 6. The roll pin secures these parts in pump housing.

Fig. 8 Collector ring-to-clutch housing seals

Fig. 9 Outer pressure plate removed

3. Install pump slide in pump housing with fluid relief hole, Fig. 5, toward housing. Place spring between slide and housing.
4. Place one vane ring in slide, then place rotor over ring, making certain pump drive slots are "down" toward seal.
5. Place pump vanes in rotor slots with polished edge of each vane against the slide inside bore. Install second vane ring.
6. Install O ring in collector ring. Use small amount of grease to hold seal in position.
7. With pump assembly facing "up", lower collector ring and reaction shaft down into pump assembly. Align dowels and bring collector ring against pump carefully. Make sure seal has not fallen from groove in collector ring.
8. Install retaining bolts and tighten alternately across bolt circle to a torque of 10-12 lb. ft.
9. Check freedom of pump rotor by inserting a small rod carefully in rotor drive notches and rotating pump rotor. Use care to prevent damaging pump seal.

Collector Ring Service

The collector ring utilizes two oil rings on the reaction shaft, Fig. 7. These rings should be replaced at each overhaul.

The roller bearing located in the collector ring can be removed. However, extreme care must be observed when removing the bearing to prevent damage to the bore of the reaction shaft. When pressing in a new bearing the lettering on the end of the bearing race must be up. Make certain that the bearing is absolutely clean. Press bearing, Fig. 7, flush to face of reaction shaft. The bearing must be flush or slightly below the face of the shaft. Use a straight edge to check the bearing location. *Do not push bearing hard into bottom of bore.*

The heat exchanger connections can be removed for cleaning purposes, Fig. 8. Note location of longer fitting for proper replacement. Also be careful not to damage the O ring seal at the end of the longer fitting when replacing. Use grease to help slip rings over threads when installing. Washers are used under each fitting.

Note location of thrust washer at converter ring hub. This washer is secured from turning by internal tangs.

Converter Clutch Service

1. Remove outer clutch pressure plate snap ring.
2. Lift out pressure plate. Note undercut face of pressure plate which is reassembled towards clutch driven disc, Fig. 9.
3. Remove clutch driven disc and hub. The longer hub section of hub is towards clutch shaft.
4. Support clutch in press to prevent damage to shaft and, using a suitable spring compressing tool, Fig. 10, remove spring load from spring retainer snap ring. Then remove snap ring.
5. Release press pressure and remove spring retainer, spring and inner pressure plate. Note that the pressure plate return spring is installed "dished side down".
6. Lift out clutch release lever assembly. Note location of rolled edge

Fig. 10 Removing spring retainer snap ring

Fig. 11 Clutch lever removal

of release lever retainer ring. The rolled edge is facing "up".

7. Remove clutch baffle plate retainer snap ring.
8. Remove baffle plate and piston return spring. Piston return spring is installed "dished side up".
9. Lift out piston assembly.
10. Remove piston oil seal ring from clutch drum hub and remove piston ring.
11. The mainshaft pilot bearing can be removed using a hooked tool working around the diameter of the bearing race to prevent binding. Remove thrust bearing and thrust washer.
12. When installing pilot bearing, be sure thrust washer is placed in bottom bore first. The thrust bearing follows, and then the pilot (roller) bearing. Press pilot bearing 1/16″ beyond face of clutch drum hub with bearing identification mark "up".
13. Reassembly of the clutch is the reverse of disassembly.

Checking Fluid Level

1. Run engine at idle speed until normal operating temperature is reached.
2. With shift lever in neutral, add fluid to bring level up to Full mark on gauge.
3. Check fluid on gauge immediately after stopping engine. This permits more accurate fluid level measurement.
4. Use only Automatic Transmission Fluid.

Changing Fluid

1. Drain fluid every 15,000 miles.
2. Run engine until it reaches normal operating temperature.
3. Stop engine, remove transmission fluid pan drain plug on the bottom of the transmission and drain.
4. Rotate converter until one drain plug appears at the lower opening of the converter housing. Loosen this plug so it acts as a vent. Then rotate the converter 180° and remove the other drain plug.
5. After draining, install and tighten all drain plugs.
6. Pour specified amount of fluid (see Transmission Index chart) in transmission.
7. Start engine and run it at idle for one minute to transfer the fluid from the transmission to the converter.
8. With engine still idling and shift lever in neutral, slowly add enough Automatic Transmission Fluid to bring the level up to the Full mark.

SELECT-O-MATIC TRANSMISSIONS

Models T-85, T-86, T-95, T-96

1. Remove shift lever housing.
2. Remove transmission companion flange with puller.
3. Remove mainshaft rear bearing cap.
4. Remove speedometer drive gear or spacer.

74. Bearing

5. Remove mainshaft rear bearing by placing bearing puller on snap ring of bearing and pull bearing.
6. Main drive gear bearing has to be removed from main drive gear before drive gear is removed from transmission case. Remove snap ring from bearing and pull bearing off shaft by using puller on snap ring of bearing.
7. Remove pocket bearing rollers from main drive gear.
8. Remove main drive gear bearing snap ring.
9. Lift mainshaft and gear assembly out of case by its front end.
10. Remove countershaft rear bearing cap.
11. Remove nut from rear end of countershaft.
12. Pull reverse idler gear shaft from case.
13. Remove reverse idler gear and bearing from case.
14. Slide countershaft far enough to the rear to allow a puller to be applied to the rear bearing and pull off the bearing.
15. Lift countershaft assembly out of case by its front end.
16. If necessary, disassemble mainshaft and countershaft and reassemble the transmission as follows:

Reassemble

1. If it has been disassembled, press new gears on the countershaft one at a time.
2. To assemble mainshaft, first place second speed gear over front end of mainshaft with clutching gear teeth and synchronizer cone toward front end of shaft.
3. Place two Woodruff keys in slots in second and third speed clutch gear positions.
4. Press on mainshaft second and third speed clutch gear.
5. Place synchronizer on clutch gear.
6. Install mainshaft third speed gear with clutching teeth and synchronizer cone toward rear of mainshaft.
7. Install sleeve with its flanged end toward rear.
8. Press sleeve into place, making sure notches in sleeve are located in correct position with Woodruff keys.
9. Install fourth speed (or overdrive) gear thrust washer on front of mainshaft and slide down splines into proper location against gear.
10. Place snap ring over front end of mainshaft into groove provided.
11. Install fourth and fifth speed synchronizer on mainshaft. When transmission is overdrive on fifth speed, the large diameter synchronizer cone is assembled toward front; when fifth is direct drive the small diameter synchronizer cone faces the front.
12. Install first and reverse sliding gear on splines on rear of mainshaft with shift fork collar toward front of mainshaft.
13. Assemble main drive gear.
14. Install countershaft assembly.
15. Install reverse idler gear assembly.
16. Install mainshaft assembly.
17. Complete the assembly of the transmission by reversing the order of its disassembly.

Metro-Matic Transmission Section

For service procedure on this transmission see the Warner Automatic transmission chapter

TRANSMISSION REPAIRS

A detailed service procedure on this transmission is given elsewhere in this book. The following material outlines the procedure for removing the transmission from the vehicle and service adjustments.

SERVICE ADJUSTMENTS

The adjustments given should be performed in the order in which they appear. Be sure that all specifications are closely adhered to.

Engine Idle Speed

Place the selector lever in Neutral and start the engine. Run the engine at idle speed until normal operating temperature is reached. Check the engine idle speed with a tachometer and, if necessary, adjust to 350-400 rpm.

If the anti-stall dashpot holds the throttle open and prevents the correct idle speed adjustment, loosen the lock nut and turn the dashpot adjusting screw in (clockwise) until the correct idle speed is reached.

Anti-Stall Dashpot

After the engine idle speed has been properly adjusted, shut off the engine and adjust the anti-stall dashpot.

Holding the throttle in the closed position, turn the dashpot adjusting screw out (counterclockwise) until the head of the screw pushes the dashpot rod up to the end of its travel. Hold the dashpot rod in this position and back off the adjusting screw four turns to obtain .100" clearance between adjusting screw and dashpot rod when the rod is fully compressed.

Manual Linkage

With the engine shut off, disconnect the manual shift rod from the selector lever on the steering column and the transmission lever on the conventional chassis, or bellcrank on the Metro Chassis.

Position the selector lever so the indicator is down against its stop in the "D" (drive) position. Place the transmission manual lever in the "D" detent (second from top of transmission).

Position the manual shift rod into the ball joint on the steering column. The opposite end of the rod should be installed in the transmission shift lever on the conventional chassis and secured with a washer and cotter pin. On the Metro chassis, the rod yoke should be positioned on the bellcrank and secured with a clevis pin, washer and cotter pin. Then tighten the ball joint nut at the steering column lever.

Move the selector lever through all positions, checking the alignment of the pointer in all positions.

Starter Neutral Switch

Check the starter circuit in all selector lever positions. The circuit must be open in all positions except "N" and "P". To adjust, loosen the neutral switch-to-steering column attaching screws. Position the switch so that the starter circuit is closed when the selector lever is at "N" or "P".

Kickdown Switch

The kickdown switch is located in the toeboard under the throttle treadle on the conventional chassis, while on the Metro chassis, the switch is mounted on a bracket under the toeboard and operated by a pad welded to one of the throttle linkage rods.

To adjust the switch on conventional chassis models, loosen the two nuts, one below and one above the toeboard. Turn the upper nut clockwise or counterclockwise to obtain the proper clearance of approximately ¼" between the switch and throttle treadle when the carburetor throttle plates are wide open.

On Metro chassis, perform the same adjustment except the ¼" clearance will be between the pad welded on the throttle linkage and kickdown switch.

Vacuum Control Unit

The vacuum control unit, located at the rear of the transmission, should be checked for proper adjustment as follows:

1. Connect a tachometer on engine.
2. Remove ⅛" pipe plug on left side of case near front of transmission.
3. Install pressure gauge connector at this location, then connect the pressure gauge inside the cab.
4. Start engine and move selector lever to "D" position.
5. Apply hand and service brakes and accelerate the engine until 1000 rpm is reached. The pressure gauge reading should be 82-88 lbs.
6. If the correct pressure is not obtained, it will be necessary to adjust the vacuum control unit. This is done by loosening the lock nut and rotating the unit. Rotating the unit clockwise increases the pressure, and vice-versa. Adjust the unit to obtain the correct pressure and tighten the lock nut. *Do not operate the engine over 10 seconds at any one interval when performing the above test.*

TRANSMISSION, REPLACE

1. Disconnect fluid filler tube at oil pan and drain fluid. Loosening the tube clip capscrew at the extension on the starting motor will permit rotating the filler tube for transmission removal.
2. Disconnect vacuum line at vacuum unit at rear of transmission.
3. Disconnect speedometer cable at transmission.
4. Disconnect hand brake cable at drive shaft brake if chassis is so equipped.
5. Disconnect shift linkage at transmission.
6. Disconnect two oil cooler lines on right side of transmission if chassis is so equipped.
7. Disconnect propeller shaft at transmission companion flange. Wire end of propeller shaft to frame to permit transmission removal.
8. Support transmission with suitable hoist or cradle.
9. Remove transmission - to - converter housing upper capscrews and insert guide studs in the holes.
10. Remove lower capscrews and pull transmission rearward and remove from under chassis.
11. Reverse the foregoing procedure to install the transmission. However, be sure to align the turbine shaft splines with the turbine hub splines, and the converter impeller lugs with the slots in the front pump drive gear.

Rear Axle Section

For Eaton and Timken (Rockwell) driving axles used on International trucks, see the "name" chapter for service procedures

Steering Gear Section

Fig. 2 Ross cam and lever steering gear with bearing mounted twin studs

Fig. 3 Ross cam and lever steering gear with bearing mounted single stud

ROSS CAM & LEVER

These steering gears, Figs. 1, 2 and 3 are of the cam and lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower stud or studs are pulled along the cam groove causing the lever arm to rotate the lever shaft. As an aid to easy steering the lever shaft stud or studs which engage the cam are mounted on tapered roller bearings. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and cam where most of the steering action occurs.

Cam End Play, Adjust

Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces. Then adjust as follows:

Twin Stud Gears—Loosen the lock nut and adjusting screw in the side cover to free the studs in the cam groove. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of adjusting shims, which are .002″, .003″ and .010″ thickness. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim. If necessary, remove or replace shims until the adjustment is correct.

Single Stud Gears—Loosen the housing side cover adjusting screw to free the stud in the cam groove. Turn down the cam adjusting plug, located at the top of the gear housing, until there is a barely perceptible drag so that the steering wheel can be turned freely with the thumb and forefinger lightly gripping the rim.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then starting from this point count the number of turns required to reach the end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but a slight drag should be felt in the mid-position only.
3. After proper adjustment is secured, tighten the lock nut and give the gear a final check for binding.

Fig. 1 Ross cam and lever twin stud steering gear

Stud Roller Bearing, Adjust

In most cases the foregoing adjustments will be adequate but it is sometimes necessary to adjust the stud roller bearing units as they should be preloaded at all times. A heavy drag should be felt when revolving the studs by hand. If a torque wrench is available the bearings should be adjusted so that the torque required to revolve the stud is as follows:

Lever Shaft Dia.	Torque, In. Lb.
1⅜″	3 to 4
1½″	3 to 4
1⅝″	4 to 8
1¾″	5 to 11

1. To adjust, remove lever shaft from housing, wash the bearings in solvent and blow dry with compressed air, using care not to spin the bearings. Lubricate the bearings with light oil.
2. Straighten out the prong of the locking washer to release the stud nut. Remove the nut and install a new locking washer.
3. While holding the stud nut from turning with a spanner wrench on the locking washer, tighten the nut as required to revolve the stud in accordance with the table above.
4. When proper adjustment has been secured, bend the prong of the washer against a side of the nut to keep it from turning.
5. Lubricate the bearings with gear oil and assemble the lever shaft in the steering gear housing.

Engine Section

ENGINE, REPLACE

1. Drain cooling system, crankcase and disconnect battery ground cable.
2. Remove fan blade, radiator, and other parts such as radiator cross braces, heater air ducts, etc., which may interfere with engine removal.
3. Remove carburetor and engine wiring.
4. Remove fuel line from pump.
5. Disconnect exhaust pipe from manifold.
6. Install lifting fixture on engine.
7. Hoist engine enough to support it while disconnecting engine front mountings.
8. Separate engine from transmission by separating transmission from flywheel housing or flywheel housing from rear of engine.
12. Remove engine from chassis.
13. Replace in reverse order of removal.

CYLINDER HEAD, REPLACE

Cylinder heads should be tightened down by starting from the center, working outward from side to side and to the ends in the sequence shown in Fig. 1.

Fig. 1 Cylinder head tightening sequence

Draw the bolts down evenly, repeating the operation until all are normally tight. After running the engine to warm it up thoroughly, a final tightening should be made with a torque wrench to the torque load listed in the *Engine Tightening Specifications* table.

ROCKER ARM SERVICE

As shown in Fig. 2, the rocker arm assembly consists of the shaft, shaft supports, rocker arms and spacers. The rocker arms are lubricated by oil supplied to the hollow shaft through an oil passage in one of the supports.

Formation of sludge in the oil passages of the rocker arms and shaft will restrict flow of oil to the rocker arm bushings and valves. Therefore, each time the assembly is removed, it should be disassembled and cleaned thoroughly.

When disassembling, keep parts in order to assure reassembly in their original position if in satisfactory condition.

If necessary to remove plugs from each end of shaft, drill or pierce one plug, then knock out the opposite plug with a steel rod. Working from other end, knock out other plug.

When reassembling, lubricate rocker arm bushings with engine oil. Make sure the notches at ends of rocker arm shaft are up. Be sure to position the rocker arm support having the oil feed hole so that the oil hole will index with the oil feed hole in the cylinder head (third from rear, Fig. 3.

Service Note

Before installing push rods rotate the crankshaft to position the crankshaft pulley hub as shown in Fig. 3. This is to prevent possible damage to engine parts if the hydraulic lifters have not leaked down to operating position.

Fig. 2 Rocker arm assembly

VALVES, REMOVE

All Engines

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

VALVES, GRIND

All Engines

Fig. 4 illustrates the recommended valve seats to be obtained. The intake seats may be narrower than the exhaust because they are usually larger in diameter, thus providing a total seat area ap-

Fig. 3 Correct position of crankshaft pulley when installing push rod

proximately equal to smaller exhaust valve with the wider seat. Also the less severe heat conditions do not require as large a seat area for heat dissipation purposes.

There are also objections to an excessively wide seat. In city or light delivery service, a wide seat collects carbon and particles of dirt that will produce variations or loss of compression, resulting in poor idle and possibly a loss of general performance and economy.

A wide seat in severe service, operating in the presence of dirt or an excess of carbon, will produce a badly pitted seat which may be just as detrimental to valve life as a too narrow seat. Under these conditions, a seat width to the minimum limit would possibly be better. However, the source of trouble (dirt, carbon) should be eliminated, making it possible to retain the wider seat.

VALVE ROTATORS

Fig. 5 illustrates the valves and related parts. Note the "Roto Cap" used with the exhaust valve.

If the special gauge is not available, a check for clearance can be made by holding the assembled valve and rotating mechanism in the hands. With one hand press down on the valve cap and with the other hand turn the valve. If the valve turns readily at least it indicates that there is clearance present.

Fig. 5 Valves and related parts

VALVE SEAT INSERTS

If replacement of a valve seat insert becomes necessary, it is important that the new insert be securely peened in place, Fig. 6, using either an insert peening tool or a dull-pointed chisel, ¼" wide, to peen the cylinder head or block metal over the outer edge of the valve seat insert.

Valve seat inserts supplied for service are standard size and a .030" oversize which permits a tight fit.

VALVE SPRINGS

All Engines

Valve springs should be checked by measuring their free length, and the uniformity should not vary more than $\frac{1}{16}$".

Each spring should also be checked for squareness. This can be done with a steel square and surface plate. Stand each spring and the square on end on the surface plate and slide the spring up to the straight edge of the square. Then gradually revolve the spring, while at the same time noticing the space between the top coil of the spring and the square. This space should not exceed $\frac{1}{16}$"; if more, replace the spring.

Valve springs should be checked for tension with a spring tester. Any spring that does not conform to the specifications listed in the chart within 10% should be replaced.

VALVE GUIDES, REPLACE

Clean valve guides with a suitable cleaning tool. Then check each valve guide with a "GO and NO-GO" gauge, if available; otherwise, use a new valve to check the fit. If the "NO-GO" portion of the gauge enters, the guide must be replaced.

Clearance in excess of .006" for intake valves and .008" for exhaust valves, calls for replacement of valve guides.

New guides should be installed so that the distance from the cylinder head to the top of the guide is as follows:

4-152 intake ..... $\frac{31}{32}$"
4-152 exhaust ..... $1\frac{3}{32}$"

When guides are properly installed, they should be reamed to the following diameters:

4-152 ..... .376-.377

VALVE LIFTERS

Hydraulic valve lifters, Fig. 7, are removed from the engine as an assembly. The lifters are removed by removing the valve cover, rocker arm and shaft assembly, then lifting out the push rods. If a lifter cannot be removed due to carbon build-up, use a carburetor solvent in the lifter bore. However, if an excessive amount of solvent is used, it will be necessary to change the engine oil. The lifters are also accessible by removal of the lifter covers.

As shown in Fig. 7, different designs of hydraulic lifters are used. When disassembling, do not mix the components

Fig. 4 Valve seat widths

of any lifter. Service kits of component parts are available for both types of lifters.

Servicing Hydraulic Lifters—Failure of a hydraulic lifter is generally caused by an inadequate oil supply, dirt or other foreign substance. An air leak at the intake side of the oil pump or too much oil in the engine will cause air bubbles in the oil supply to the lifters, causing them to collapse. This is a probable cause of trouble if several lifters fail to function, but air in the oil is an unlikely cause of failure of a single unit.

In servicing the lifters particular attention should be given the plunger and valve. The plunger should be checked for signs of scoring or wear, and the valve for pitting. Check the valve seat in the end of the plunger for any condition that would not allow the valve to seat perfectly. If any of the above conditions are apparent, install a new lifter assembly.

Do not disassemble a lifter in dirty surroundings or on a dirty work bench. Use clean paper on the bench and, after the lifter has been disassembled, place

Fig. 6 Magnified view showing how cylinder head metal should be peened to secure valve seat insert in place

Fig. 7 Hydraulic valve lifters

the loose parts in a numbered rack with the parts of each unit together. Then submerge in clean kerosene as a protection against dirt or corrosion.

With more than one lifter disassembled it is imperative to keep the parts of each lifter separate. The plunger and valve must always be fitted in the same body.

Disassemble Lifter—With a suitable tool, pry out the plunger retainer ring. Clean varnish deposits from inside the lifter body above the push rod seat. Then invert the lifter body and drop out the parts.

Cleaning Lifters—Wash all lifters in a suitable solvent that will remove all trace of varnish and carbon (paint thinner will do). Then, working on one lifter at a time and using clean lint-free cloths, thoroughly wipe off all parts. Clean the plunger and the internal and external surfaces of the body with a hard wiping action to remove any varnish residue.

To insure absolute cleanliness of a reconditioned lifter assembly, it is advisable to service one at a time, assembling it before working on the next one.

Inspection—Inspect the lifter body for blow holes and scoring. Replace entire unit if body is roughly scored or grooved.

Using a magnifying glass, inspect the check valve seat for defects. Inspect the outer surface of the plunger for scratches or scores. Defects in the check valve seat or scores or scratches on the outer surface of the plunger which can be felt with the fingernail are causes for replacing the entire unit.

Replace the push rod seat if the area where the push rod contacts is rough or otherwise damaged.

Using a magnifying glass, carefully examine the check valve for nicks, imbedded material or other defects which would prevent proper seating. Even though no defects are found it is advisable to discard the old valve and use a new one when servicing a lifter.

Assembling Lifters—Rinse all parts in clean kerosene and assemble without drying. This will avoid the adherence of dust or lint if they are blown off or wiped with cloth.

Place the parts in the body in the following order: spring, valve and plunger. The plunger must slide freely in the body. Place the push rod seat on the plunger and depress these parts and install the plunger retainer in the groove in the body.

TIMING GEARS

When valves are correctly timed, the timing marks on the gears or sprockets should be adjacent to each other.

CAMSHAFT & BEARINGS

Camshaft bearings should be installed in sets and care must be exercised to see that the oil holes in the bearings and the oil feed holes in the block are aligned to assure adequate lubrication.

Camshaft bushings must be installed so as to provide running clearance between valve lifters and bushings as shown in Fig. 8.

PISTONS & RODS, REMOVE

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals.

Make sure rods and pistons are properly numbered so they can be reinstalled in their proper cylinders. It is advisable to install the caps on the rods to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

For correct assembly of the connecting rod to the piston, the rod bearing locators (bearing tangs) must be toward the dome side (marked "up") of the piston. And when installed in the cylinder, the word "up" on the piston goes toward the top (camshaft) side of the engine.

PISTONS, REPLACE

When fitting a piston, wipe the cylinder wall clean with a cloth and insert the piston upside down in the bore (rings and pin removed). Use a ½" wide feeler gauge which is long enough to extend the full length of the piston. The thickness of the feeler should be the same as the piston clearance given in the chart.

With the feeler hooked to a spring scale it should require the number of pounds given in the table to withdraw the feeler gauge from between the piston and cylinder.

NOTE—When steel-band-in-skirt pistons are used, the tolerances are held much closer than for other types. Furthermore, the feeler gauge method of checking this clearance is not practical. To attain proper fitting use micrometers for making piston selection and then check clearance as follows:

1. Wipe both piston and cylinder wall with clean, dry cloth.
2. Install piston top downward into cylinder.

Fig. 8 Checking clearance between valve lifters and camshaft bearings

3. A non-knurlized piston should be fitted so that there is .0008" to .0013" running clearance. This clearance will permit the piston to fall slowly through the cylinder bore of its own weight.
4. Knurlized pistons should fit slightly closer. These pistons are fitted so there is a slight drag (1 to 2 lbs.) to a light push fit in the cylinder bore.

PISTON RINGS, REPLACE

Always use standard size rings in cylinder bores that are standard at the bottom, regardless of the amount of taper in the bore. Oversizes must be determined by the measurement of the narrowest portion of the bore.

New rings should be fitted according to the instructions furnished with the ring package. Ring grooves must be clean and free from carbon and must show no perceptible wear.

PISTON PINS, REPLACE

Piston pins are a press fit in the connecting rod. The fit should be .0006-.0012" in the rod and .0005-.0009" loose in the piston.

ROD BEARINGS, REPLACE

These bearings are of the precision insert type, requiring no scraping or reaming.

When installing bearings, be sure the back of the bearing shells as well as the bearing seats in the rods are smooth and clean.

Bearing clearance may be checked with Plastigage, which is available at any auto parts jobber. Instructions for its use are furnished with the package.

Lacking Plastigage, however, use a piece of tough paper or shim stock ¾" square which measures about .0005" under the maximum allowable bearing clearance. Oil the shim on both sides and lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap bolts to normal tension.

The clearance is correct if the rod can be moved endwise when tapped lightly with a hammer. If the rod can be moved endwise by hand, clearance is too great. On the other hand, if the rod will not move when tapped lightly with a hammer, not enough clearance is present.

When using a torque wrench tighten bearing caps to the torque loads given in the table.

MAIN BEARINGS, REPLACE

These bearings are of the insert type, requiring no reaming or scraping. They may be removed and replaced without removing the crankshaft.

Plastigage may be used to check bearing clearances, and instructions for its use are furnished with the package.

Lacking Plastigage, an alternate method is to use a piece of tough paper or shim stock 1" square which measures about .001" under the maximum allowable bearing clearance. Oil the shim on both sides and lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap bolts to normal tension.

Rotate the crankshaft through a two-inch arc (one each way) and if it is movable with a fairly heavy drag, the clearance is correct. If there is no perceptible drag, the clearance is too great. On the other hand, if the shaft cannot be moved, not enough clearance is present.

Be sure that the bearings are smooth and clean on both sides when installed. This applies to the bearing seats as well.

When using a torque wrench, tighten bearing caps to the torque loads given in the table.

CRANKSHAFT OIL SEAL, REPLACE

The rear main bearing oil seal can be replaced with the engine in the chassis by first removing the transmission, clutch and flywheel.

OIL PUMP REPAIRS

Conventional gear type oil pumps, located in the crankcase, are used on all engines. After removing the oil pan, the pump may be unfastened from its mounting and disassembled for repairs.

Inspect the pump gears for nicks or burrs. Inspect the bottom cover for wear and dress down on a surface plate with emery if necessary. Place the bottom cover on the pump and check the drive shaft end play. If end play is excessive (more than .006"), replace the drive and idler gears.

Service Note

Whenever the oil pump is removed, the distributor will have to be taken off as well in order to reinstall the pump without damage. The reason for this is that the slots in the end of the oil pump drive shafts must match the tangs on the end of the distributor drive shaft. If an attempt is made to install the pump while the distributor is in place, it will be difficult or impossible to align the slots and tangs with the result that the pump will be damaged when its mounting bolts are tightened. Be sure to retime the ignition when the oil pump and distributor are installed.

Fig. 9 Holley 1904 carburetor

Fig. 10 Setting float level with gauge

Fig. 11 Setting float level without gauge. Dimension indicated should be 13/64"

WATER PUMP REPAIRS

The pumps used on these engines are of the sealed ball bearing type packed with lubricant at the time of assembly and requiring no further lubrication. When disassembling, carefully note the arrangement of the seal parts so that correct assembly may be assured.

Never soak the shaft and bearing assembly in cleaning solvent because it will dissolve the lubricant. To clean the shaft and bearing, merely moisten a cloth with cleaning fluid and wipe away any surplus lubricant or other foreign matter.

Be sure the face of the housing against which the thrust washer turns is smooth and true. If not, smooth it up with a special water pump facing cutter.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

CARBURETOR

Holley 1904, Fig. 9

Float Level: Invert main body, allowing float to drop to the closed position. Using float gauge shown in Fig. 10, check the setting on both the "touch" and "no touch" legs of gauge. The level of the float may be adjusted by bending the small tab in the float lever which contacts the head of the fuel inlet needle pin. Use needle nose pliers for this adjustment and recheck the setting after adjustments have been made.

If the gauge is not available, measure from the roof of the float chamber to the lowest point of the float, Fig. 11, with carburetor inverted.

Idle Adjustment: When the engine has reached normal operating temperature, after first checking to be sure that the choke plate is wide open, adjust the throttle stop screw to idle the engine at 350 rpm.

Set the idle mixture adjusting needle to give the highest steady manifold vacuum. If a vacuum gauge is not available, adjust it to the smoothest maximum idle speed. Should the adjustment result in an excessive increase in the idle rpm, reset the throttle stop screw to obtain the specified rpm.

Clutch, Transmission & Rear Axle

Fig. 1 Disassembled view of transmission

CLUTCH, REPLACE

When removing the transmission for the purpose of gaining access to the clutch or for any other reason, extreme care should be taken to support the weight of the transmission until it is completely removed so that the clutch shaft splines will clear the clutch disc hub. There is a possibility of distorting the clutch disc which will then not permit a free release of the clutch.

When installing the clutch, position the disc and clutch assembly on the flywheel, using a stub shaft (or a spare clutch shaft) to align the clutch disc. Then tighten the cover-to-flywheel capscrews gradually and evenly.

Free Pedal Travel, Adjust

The clutch pedal should have a minimum of 1½" free movement before clutch pressure is felt. If pedal free movement is less than specified, an adjustment is necessary to provide adequate bearing-to-lever clearance.

On models with turnbuckle release rod, adjustment is made by loosening release rod lock nuts on each side of turnbuckle. Looking down on turnbuckle, turn it counter-clockwise to increase or clockwise to decrease free travel.

On models with adjustable end yokes, remove yoke pins and turn yokes up or down on release rod as required.

TRANSMISSION

Disassemble, Figs. 1 & 2

1. Remove gearshift housing.
2. Remove parking brake.
3. Remove mainshaft bearing retainer.
4. Drive countershaft out through rear of case.
5. Use puller to remove mainshaft bearing.
6. Remove input shaft retainer and tap shaft and bearing as far forward as possible.
7. Remove mainshaft assembly.
8. Remove input shaft. If bearing is to be replaced, assemble with thickest snap ring that will fit.
9. Use puller to remove reverse idler shaft.
10. Remove reverse idler gear and countershaft gear cluster.

Assemble Transmission

1. Install reverse idler gear and shaft.
2. Install cluster gear assembly with front thrust washer tip hooked into groove on inside of case. Check end play (.006-.020"). Change thrust washers as required.

3. Install assembled mainshaft. Place a short 2 x 4 block between input shaft and mainshaft. Slide mainshaft bearing baffle and bearing onto shaft. Baffle must be installed so it does not rub bearing outer race. Drive bearing onto shaft.
4. Install mainshaft pilot rollers in input shaft, holding them with grease.
5. Place front blocking ring on synchronizer and start input shaft bearing in case.
6. Drive mainshaft bearing into case.
7. Tap input shaft and bearing into place. Install retainer without gasket and tighten bolts to bottom retainer on snap ring. With feeler gauge, check clearance between gasket surface and case. Select a gasket or gaskets that will seal oil and eliminate all clearance.
8. Raise cluster gear and insert countershaft. Then install retainer in notches in countershaft and reverse idler shaft. Drive both shafts toward front so that retainer is tight against gasket and torque bolts to 25-37 ft. lbs.
9. Install speedometer gear and spacer, mainshaft bearing retainer and gasket, and parking brake. Tighten output shaft nut to 90-125 ft. lbs.
10. Install gearshift housing.

Fig. 2 Disassembled view of gearshift housing

SPICER REAR AXLE

Integral Housing Type

Inasmuch as the axle tubes are pressed into the differential carrier to form a one-piece housing, the rear axle assembly must be removed from the chassis when it becomes necessary to overhaul the unit.

Axle Shaft, Remove

1. Raise vehicle and place stand jacks under rear axle housing.
2. Remove wheel and brake drum.
3. Remove four nuts from bearing retainer bolts on inside of axle flange.
4. Attach axle shaft puller and remove axle shaft and bearing assembly.
5. Install bolt and nut to hold brake backing plate on axle housing.

Bearing or Oil Seal, Replace

1. With a chisel, nick soft ring next to bearing and remove ring. The ring need not be split, only nicked deep enough to allow removal.
2. Install a suitable press plate between axle flange and bearing and press bearing from shaft.
3. To replace oil seal, pry it out of housing with screwdriver.
4. Install new seal.
5. Install new bearing, pressing it on so it seats on the shaft against shoulder. Bearing retainer must be on axle shaft before bearing is installed.
6. Install new bearing retainer ring, being sure ring seats against bearing.

Axle Shaft, Install

1. Insert five new bolts and force heads down to flange on new axle.
2. Peen end of shoulder on bolts into countersink around bolt holes in flange.
3. Install new bearing as outlined above.
4. Remove temporary nut and bolt holding brake backing plate in place.
5. Install new retainer gasket.
6. Install axle shaft in housing. Outer race of bearing must seat against shoulder in axle housing.
7. Install nuts and washers on bearing retainer bolts and tighten securely.
8. Install brake drum and wheel.

Fig. 3 Disassembled view of rear axle. Front driving axle is similar

Rear Axle Assembly, Replace

Inasmuch as the axle tubes are pressed into the differential carrier to form a one-piece housing, the rear axle assembly must be removed from the chassis when it becomes necessary to overhaul the unit.

1. Raise vehicle from floor and support with stand jacks under frame side rails.
2. Remove rear wheels.
3. Split rear universal joint.
4. Disconnect parking brake cable from equalizer rod and unfasten brake cable brackets from frame cross member.

Fig. 4 Spicer semi-floating axle showing adjusting points

Fig. 5 Prying differential from housing. Spicer axle

Fig. 6 Checking clearance between bearing cup and differential case. Spicer axle

5. Disconnect hydraulic brake line connection at rear axle housing.
6. Loosen and move shock absorbers out of the way.
7. While supporting axle housing with hydraulic jack, remove spring clips and lower axle assembly to the floor.
8. Reverse the foregoing procedure to install the rear axle assembly, being sure to bleed the brake system when the installation is completed.

Disassemble, Fig. 3

1. Remove axle shafts. Axle shafts may be pulled out only far enough to clear differential side gears.
2. Drain lubricant and remove rear cover.
3. Make sure differential side bearing caps and axle housing are marked, then remove the side bearing caps.
4. Pry differential from housing, Fig. 5.
5. Remove side bearing cups.
6. Pull off side bearing and adjusting shims, tagging the shims for identification on reassembly.
7. Unfasten ring gear from case.
8. Drive out differential pinion shaft pin and pull out the shaft, pinions and side gears.
9. Hold companion flange from turning and remove flange nut.
10. Pull flange from pinion shaft.
11. Remove pinion from carrier by tapping on front end with soft hammer.
12. Remove pinion shaft bearing oil seal and bearings from carrier, keeping separate the shim pack at each bearing.

Pinion & Bearings, Replace

If the original ring gear and pinion are being used in the original carrier, use the original shim packs at each bearings, Fig. 4. If a new pinion or differential carrier is installed, note the markings on the end of the pinion gear and on the differential carrier to obtain the correct thickness of shimming to be used with these parts from your supplier. The shims behind the rear bearing establish the correct pinion depth.

1. Press the rear pinion bearing cup in the housing with the proper thickness of shims. Press the rear pinion bearing on the shaft.
2. Install the front bearing cup and shims, and front bearing.
3. Install the companion flange and, while holding the flange from turning, tighten the nut to a torque load of 200-220 lb. ft.
4. Check the pinion bearing pre-load with a spring scale and heavy cord wrapped around the companion flange. Pull on the spring scale. The torque required to rotate the pinion is 10-30 inch lbs. If not within these limits, add or remove shims from behind the front bearing to obtain the proper pre-load.
5. Remove the companion flange and install a new oil seal (well soaked). Reinstall the companion flange and tighten the nut to a torque load of 200-220 lb. ft.

Ring Gear, Replace

1. Install guide pins in every other hole in the ring gear. These pins can be made from 1½" long capscrews with heads cut off and ends slotted.
2. Make sure back face of ring gear and face of case are free of dirt and burrs and slip gear over pilot diameter of case.

Fig. 7 Installing differential and bearing cups. Spicer axle

Fig. 8 Method of correcting backlash between ring gear and pinion. Spicer axle

Fig. 9 Proper tooth contact. The tooth bearing both lengthwise and profile should appear as shown

3. Install every other ring gear bolt. Draw them up evenly and snugly so ring gear face is flush with face of case.
4. Remove guide pins and install remaining bolts.

Fig. 10 Not enough backlash. Move ring gear away from pinion

Fig. 11 Too much backlash. Move ring gear toward pinion

Fig. 12 Pinion in too far. Move pinion away from ring gear

Differential Carrier, Assemble

The differential bearings are adjusted by shims, Fig. 4. These shims also establish the ring gear position with the pinion. Therefore, backlash must be checked whenever a bearing adjustment is made.

The correct bearing adjustment is one which will provide a .015-.020″ pinch fit when the differential unit is assembled into the carrier. To make the adjustment, install the bearing cones without shims and place the assembly in the housing with the bearing cups. Force the unit to one side and check the clearance between the bearing cup and differential case with a feeler gauge, Fig. 6. When the clearance is determined, select shims of this amount plus .015-.020″ extra to establish the proper pre-load.

Remove the differential bearings again and divide the shims into two packs of equal thickness and install on each side and replace the bearings. Reinstall the unit in the carrier. This operation is made easier by cocking the bearing cups slightly when the differential is placed in the housing and then tapping them lightly with a mallet, Fig. 7.

Fig. 13 Pinion out too far. Move pinion toward ring gear

However, when installing the differential in the housing, be sure the ring gear teeth mesh with the pinion teeth before tapping the bearings in place.

After the bearing cups are firmly in place, install the bearing caps. The bearing caps and gasket surface of the housing are marked with a horizontal numeral and on the other side by a vertical numeral. The position of the numerals should correspond when reinstalling the bearing caps.

Ring Gear & Pinion Backlash, Adjust

Mount a backlash gauge indicator on the carrier and start checking for the correct backlash between the ring gear and pinion. If the backlash is not within the limits of .004″ to .009″, it will be necessary to change the arrangement of the shims back of the bearings. Make corrections in backlash according to Fig. 8, bearing in mind that shims removed from one side must be installed on the opposite side so that the total shim thickness of the right and left side will remain unchanged, and the bearing adjustment undisturbed.

Gear Tooth Contact Pattern

Allowable variations in the carrier or drive pinion may cause the pinion to be too far in or out even when shimmed properly. Thus, the tooth contact must be tested and corrected as necessary or the gears may be noisy.

Paint the ring gear teeth with a light coating of red lead, white lead or prussian blue. Revolve the gears and observe the contact, referring to Figs. 9 to 12.

Front Driving Axle & Steering Gear

FRONT DRIVING AXLE

The differential carrier assembly is the same as the rear driving axle except that the front unit is full floating. The axle shafts can be removed without dismantling the steering knuckles.

Axle Shaft & Universal Joint

Removal

1. Referring to Figs. 1 and 2, remove hub cap and wheel.
2. Remove grease cap and snap ring.
3. Remove drive flange and gasket.
4. Remove brake drum.
5. Remove wheel bearing adjusting nut and washer.
6. Remove wheel hub with wheel bearing, taking care not to damage oil seal.
7. Disconnect brake hose at backing plate.
8. Remove six backing plate and wheel spindle bolts and washers.
9. Remove wheel bearing spindle with bushing.
10. Pull axle shaft and universal joint from axle housing.

Installation

1. Clean dirt from all parts.
2. Enter shaft and joint assembly into housing. Enter spline end of axle shaft into differential and push into place.
3. Install wheel bearing spindle with bushing.
4. Install backing plate and brake hose.
5. Pack wheel bearings with lubricant and install.
6. Assemble driving flange, wheel hub and drum.
7. Install wheel bearing lockwasher and adjusting nut. Tighten adjusting nut until there is a slight drag on bearings when hub is turned, then back off 1/6th of a turn.
8. Install lockwasher and lock nut; tighten nut and bend lip of lockwasher over lock nut.
9. Install snap ring, grease cap, wheel and hub cap.

Steering Knuckle Bearings

Replacement of steering knuckle bearings or bearing cups on the kingpin requires removal of the tie rod, brake drum, hub, wheel bearing, axle shaft, spindle and steering knuckle. The following procedure should be followed when removing the steering knuckle:

1. Referring to Figs. 1 and 2, remove studs and tapered capscrews holding kingpin bearing lower cap.
2. Remove studs and tapered capscrews holding kingpin bearing upper cap and shims.
3. Remove eight oil seal retaining capscrews.
4. Remove upper and lower steering

Fig. 1 Disassembled view of axle shaft and universal joint

Fig. 2 Sectional view of front wheel, steering knuckle, axle shaft and universal joint

knuckle bearing cone and cup.

5. Remove steering knuckle and seals.

Installation: When reinstalling the steering knuckle, sufficient shims must be installed under the upper bearing cap so the proper tension may be maintained on the knuckle bearing. No shims are used on the lower bearing cap.

Shims are available in thicknesses of .005", .010", and .030". Install one each of the three thicknesses over the studs on top of the knuckle. Then proceed as follows:

1. Install wheel bearing cups and cones, steering arm, bearing cap, bolts, lockwashers and nuts.
2. Check tension of bearings by hooking a spring scale around the steering arm ball.
3. Pull the scale at right angle to the steering arm. Take the reading when the arm is moving.
4. Remove or add shims until the load is approximately 25-35 pounds without the oil seal assembly in position.

Steering Knuckle Oil Seal

To remove the seal, remove the eight capscrews holding the steering knuckle oil seal in place and remove the seal.

Before installing the new seal, examine the spherical surface of the axle for scores or scratches that might damage the new seal. Roughness of any kind should be smoothed with fine emery cloth.

Lubrication

The front axle universal joints are lubricated by a constant supply of lubricant in the steering knuckle housings. A level plug for checking the lubricant level is located at the rear of each housing. Every 1,000 miles the level should be checked. The recommended capacity for each steering knuckle housing is 38 oz. Use viscous chassis lubricant. *If necessary to overhaul the universal joints, see the Universals chapter.*

STEERING GEAR

When making adjustments on the steering gear, Fig. 3, free the gear of all load, preferably by disconnecting the drag link from the steering arm, and loosen the instrument panel bracket clamp on the steering gear jacket tube. If the ball thrust bearings on the cam must be adjusted, make this adjustment first before making the side adjustment to the lever shaft stud in the cam groove.

Ball Thrust Bearing On Cam, Adjust

1. Referring to Fig. 4, loosen the housing side cover adjusting screw to free the studs in the cam groove.
2. Adjustment should be made so there is a very slight drag but not so much that the steering wheel cannot be turned from one extreme to the other by lightly gripping the wheel rim with thumb and forefinger.
3. Unscrew the four screws and raise the housing upper cover to permit removal of shims.
4. Clip and remove a thin shim or more as required and draw cover down tight against shims.
5. Test as outlined in Step 2 and if necessary, remove or replace shims until adjustment is correct.

Lever Shaft Stud, Adjust

1. Backlash at this point shows up as end play of lever shaft, also as backlash at steering wheel and at ball on steering arm.
2. The groove is purposely cut deeper in ends of cam than at mid-position. This produces a high range through mid-position and makes grooves narrower through this range. This permits take-up of backlash in mid-position, after normal wear of

Fig. 3 Steering gear assembly

Fig. 4 Steering gear adjustments

groove, without causing a bind in the ends.

3. Adjust to this mid-position high range only. Play in end position is not objectionable.
4. Tighten side cover adjusting screw until a very slight drag is felt through the mid-position when turning steering wheel slowly from one extreme position to the other. *Steering gear must not bind in any position. Only a very slight drag should be felt. A closer adjustment will not correct steering looseness caused by wear in other steering gear units, but will damage parts and impair operation.*
5. When proper adjustment has been made, tighten locknut and check adjustment.
6. Make sure steering gear arm is tight on splined lever shaft and that lockwasher and nut are tight also.

①—120 lbs. ft. on older blocks not identified by 150 mark adjacent to casting number.

ENGINE TUNE-UP

Caution—Some of the adjustments given below require breaking one or more of the tamper-proof seals protecting the injection pump and governor and should be performed only by a Mack Branch or Bosch Service Station. Breaking any of these seals voids all warranty.

Fuel System

The following procedure is a guide for restoring engine and accessory equipment to original specifications. Before proceeding, loosen fuel tank sump plug to drain sediment and water, clean sump of primary filter and change element of secondary filter. Operate hand priming pump to bleed air from lines.

Air Cleaner

Remove oil reservoir and element. Remove sludge from reservoir, clean element in suitable cleaning solvent and allow to dry. Dip element in engine oil, allow to drain and reinstall in housing. Fill reservoir to level mark with engine oil and reinstall baffle and reservoir. Check all connections from air cleaner to inlet manifold for tightness and possible air leaks.

Cylinder Head Stud Nuts

Check tightness of cylinder head stud nuts after engine has cooled. *Do not check with engine hot.* Tighten nuts in

ENGINE SECTIONED FROM THE REAR

ENGINE SECTIONED FROM RIGHT SIDE

ENGINE SECTIONED FROM THE FRONT

the sequence shown in Fig. 1 to 150 ft. lbs.

A special offset wrench is available through Mack (17-T-169A) for tightening nuts close to the rocker arm brackets. Lacking this tool, it is recommended that the rocker arm assemblies be removed to permit proper tightening.

Valve Clearance

With engine running at idling speed, check clearance between valve stem and rocker arm ends, when water and oil have reached a steady temperature, to a clearance of .014″ intake, .022″ exhaust. This is hot idle clearance. A cold engine requires about ½ hour of idle running and the engine of a vehicle just off the road should be allowed to idle about 15 minutes to bring about a normalizing action necessary before making this check.

Compression

Start engine. When water temperature reaches 160°F. stop engine, remove injection nozzle holder from No. 1 cylinder and install compression gauge. Restart engine and run at 1000 rpm. Pressure should be 595 psi and not below 525 psi on ENDT engines; on END engines, pressure should be 550 psi and not below 500 psi. Variation between cylinders must not exceed 50 psi. Reinstall nozzle holder after checking as outlined below. Repeat compression test for each cylinder. If any cylinder does not come up to above specification, the cause of the loss of compression must be determined and corrected.

Injection Nozzles

When each injection nozzle is removed to allow installation of the compression gauge, the nozzle should be cleaned with a bronze wire brush (Mack Tool No. 17-T-112) without disassembly from the holder. Test nozzle for leaks and for 2300 to 2350 psi opening pressure. Install a reconditioned nozzle if not satisfactory. Remove carbon from engine nozzle port using a suitable reamer (Mack Tool No. 17-T-11103). Blow out loose carbon and install nozzle, using new gasket. Tighten stud nuts to a torque of 168 to 204 *inch lbs.*

Injection Timing

Stop engine and thoroughly clean away all dirt from around the delivery valve holder at No. 1 cylinder of injection pump. Remove delivery valve holder from pump. Remove delivery valve spring and delivery valve; then replace valve holder and tighten. Operate hand priming pump slowly to provide ample fuel for timing check but do not build up pressure and risk making false reading.

Port Closing Test—Crank engine until No. 1 piston is at approximately 35° BTDC on the compression stroke. Set and hold throttle in full open position. Start to stroke the transfer pump slowly. When fuel flows from delivery valve holder, have helper crank engine very slowly until flow from delivery valve holder just ceases. Note timing at flywheel.

Perform test twice to insure accuracy. Unless flow ceases exactly at 29° BTDC on ENDT engine or 27° BTDC on END, proceed to retime injection pump as follows:

Adjustment—Remove cover held onto engine timing gear cover by eight capscrews, exposing the driven gear and hub. Loosen four capscrews in the hub and turn hub in the direction indicated by flywheel reading (index mark toward "R" on gear to retard or toward "A" to advance). One division on hub equals 4 degrees on the flywheel. For example, if fuel flow ceased at 31° BTDC, rotate hub so index mark is one division closer to "R" on gear. Tighten capscrews and repeat port closing test.

An alternate procedure if necessary to adjust is as follows: Set flywheel to exactly 29° BTDC on ENDT engine or 27° BTDC on END engine. Loosen four capscrews in the gear hub and turn counter-clockwise as far as it will go. Then turn hub slowly clockwise until fuel flow just ceases. Tighten capscrews and repeat port closing test.

When adjustment is obtained so fuel flow ceases at the correct time, replace pump drive cover, reinstall delivery valve and spring and reconnect fuel line.

Fig. 1 Tighten cylinder heads in sequence shown to a torque of 150 lbs. ft.

Injection Pump Rack Setting

With engine stopped, remove dust cover covering rack on front end of injection pump. Work throttle from idle to full on position several times and hold manually at the full on position. Use universal rack extension gauge (17-T-11245) and check measurement

AUXILIARIES SECTIONED FROM RIGHT SIDE

in accordance with "P" number of injection pump. When using gauge, make certain that gauge legs are flat against face of pump. If necessary to adjust the rack to obtain this setting, first remove the inspection cover from the top of the governor housing.

On END engines, note that with full open throttle the nose of the cam will bear against the stop plate, Fig. 2. First check the cam angle and adjust cam if necessary. Make certain lock nut is tight. Then adjust the stop plate by means of the two adjusting nuts to obtain correct rack extension (1.484″), Fig. 2, as cam nose bears against the plate. Tighten the adjusting nuts and replace inspection cover with gasket on top of governor housing. Remove gauge and replace cap before starting engine.

On ENDT engines, check the cam angle and cam plate clearance, Fig. 2. If not correct, adjust by means of the cam angle adjusting screw. Recheck cam angle. Now adjust the rack by means of the two nuts shown in Fig. 3 to obtain the correct extension dimension. Recheck cam-to-cam plate clearance (.087″) to make sure it has not changed by setting the rack. Tighten rack adjusting nuts and replace inspection cover with gasket on top of governor housing.

Mechanical Governor Adjustment

Check idling (550 rpm) and no-load governed speed (2250 rpm) with engine at operating temperature and using a precision tachometer. Adjustments may be made at the box behind the operating lever on the side of the governor, Figs. 4 and 5.

For idle speed adjustment, Fig. 4, loosen the lock nut and turn the screw IN to increase and OUT to decrease idle speed. When checking idle speed on bus with torque converter, the shift lever should be in the forward position and the idle speed is 550-575 rpm.

To adjust governed no-load speed, it is necessary to remove the stop flange covers. Loosen the lock nut and turn the screw, Fig. 5, OUT to increase and IN to decrease governed speed. At the correct setting of 2250 rpm the full-load speed will automatically be correct. Tighten lock nuts and replace covers.

TROUBLE SHOOTING GUIDE

Before consulting the guide make sure the following items have been checked and found satisfactory:

1. Batteries fully charged and all electrical connections tight.
2. Starter switch and starter in good condition.
3. Fuel in tank and system primed.
4. Lubricating oil at proper level and clean.
5. No restriction in air intake system.
6. Engine cooling system in good condition.
7. Fuel lines, suction and pressure connections tight.
8. All gauges and meters read properly.

Engine Cranks, Will Not Start

Fuel Pressure Normal:

1. Emergency shut-off cock closed or partly closed.
2. Air intake manifold valve closed or partly closed.
3. Low ambient air temperature; use starting aid.
4. Governor throttle shaft linkage binding, or sticky governor parts.
5. Injection pump rack stuck.
6. Hydraulic Governor Installation:
   a. Pressure relief valve spring broken.
   b. Pressure relief valve stuck open.
   c. Shut-down valve stuck or open.
   d. Air in governor oil feed, insufficient oil pressure.
   e. Loose governor ball-head drive assembly; excess ball-head tang clearance.
   f. Incorrect speed droop setting or length of speed follower spring.
7. Injection pump internal adjustment incorrect.
8. Worn injection pump shaft bearings.
9. Loose injection pump drive assembly; timing incorrect.

Fuel Pressure Low:

1. Air intake manifold closed or partly closed.
2. Fuel tank vent restricted.
3. Fuel supply pump inoperative or leaking.
4. Air leaks or restriction on suction

Fig. 2 Injection pump rack setting, END engine. Static fuel rack dimension is 1.484″

Fig. 3 Injection pump rack setting, ENDT engine. Static fuel rack dimension is 1.446″ with P4 pump and 1.428″ on P7 pump

Fig. 4 Idle speed adjustment on mechanical governor

Fig. 5 Governed no-load speed adjustment on mechanical governor

side of fuel system.
5. Fuel filters clogged.
6. Fuel tank or filters cracked; drain plugs loose.
7. Filter air bleed too large or missing.
8. Filter air bleed plugged.
9. Injection pump overflow valve leaking, stuck open or closed.

Fuel Pressure High:
1. Emergency shut-off cock closed or partly closed.
2. Injection pump rack stuck.
3. Broken governor throttle spring or linkage disengagement.

Engine Starts, Erratic Firing, All Cylinders

Low Fuel Pressure:
1. Emergency shut-off cock closed or partly closed.
2. Fuel tank vent restricted.
3. Fuel supply pump inoperative or leaking.
4. Air leaks or restriction on suction side of fuel system.
5. Fuel filters clogged.
6. Fuel tank or filters cracked; drain plugs loose.
7. Filter air bleed too large or missing; air-bleed plugged.
8. Injection pump overflow valve leaking, stuck open or closed.

Erratic At Idle Speed Only; Adequate Fuel Pressure:
1. Improper setting of governor idle speed.

Erratic At Both Idle and High Speeds; Fuel Pressure Adequate, Smoke:
1. Air intake manifold valve closed or partly closed.
2. Restricted air intake; clogged air cleaner (Turbocharger).
3. Injection pump internal adjustment incorrect.
4. Worn injection pump shaft bearings.
5. Loose injection pump drive assembly; timing incorrect.
6. Poor engine compression.
7. Filter air bleed plugged.
8. Faulty nozzle spray; leaky; opening pressure incorrect.
9. Nozzle cap nut improperly torqued.
10. Nozzle pintle stuck.
11. Bent or broken spindle or spring.
12. Nozzle improperly installed in cylinder head (binding).
13. Blow-by at crankcase breather.
14. Improper valve clearance; camshaft or lifters worn.
15. Broken or weak valve springs.
16. Valve guides worn or gummed.
17. Valves stuck or burned; poor seat contact.

No Smoke:
1. Fuel tank vent restricted.
2. Fuel supply pump inoperative or leaking.
3. Air leaks or restriction on suction side of fuel system.
4. Fuel filters clogged.
5. Fuel tank or filters cracked; drain plugs loose.
6. Filter air bleed too large or missing; air bleed plugged.
7. Governor throttle shaft linkage binding; sticky governor parts.
8. Improper setting of governor throttle linkage.
9. Governor drive assembly binding.
10. Broken or weak speeder springs.
11. Solenoid stuck.
12. Loose governor ball-head drive assembly; excess ball head tang clearance (hydraulic governor).
13. Improper rack, gap, cam angle or cam plate setting (mechanical governor).
14. Incorrect speed droop setting, or length of speed follower spring (hydraulic governor).
15. Injection pump overflow valve leaky, stuck open or closed.
16. Injection pump plunger stuck; rack stuck; pump plungers worn.
17. Injection pump internal adjustment incorrect.
18. Worn injection pump shaft bearings.
19. Loose injection pump drive assembly; timing incorrect.
20. Leaky cylinder head gasket; leaky gaskets or seals.

Engine Missing On One or More Cylinders

At Idle Speed Only:
1. Improper setting of governor idle speed.
2. Poor compression.
3. Delivery valve stuck or leaking.
4. Faulty nozzle spray, leaky, opening pressure incorrect.
5. Nozzle cap nut improper torqued.
6. Nozzle pintle stuck.
7. Bent or broken spindle or spring.
8. Nozzle improper installed in cylinder head (binding).
9. Injection pump plunger stuck; pump rack stuck; pump plungers worn.
10. Injection pump internal adjustment incorrect.
11. Worn injection pump shaft bearings.
12. Loose injection pump drive assembly; timing incorrect.

Missing At High and Idle Speeds, Smoke:
1. Injection pump internal adjustment incorrect.
2. Worn injection pump shaft bearings.
3. Loose injection pump drive assembly; timing incorrect.
4. Faulty nozzle spray, leaky, opening pressure incorrect.
5. Nozzle cap nut improperly torqued.
6. Nozzle pintle stuck.
7. Bent or broken spindle or spring.
8. Nozzle improperly installed in cylinder head (binding).
9. Poor Compression.
10. Blow-by at crankcase breather.
11. Leaky cylinder head gasket; leaky gaskets or seals.
12. Improper valve clearance; camshaft or lifters worn.
13. Broken or weak valve springs.
14. Valve guides worn or gummed.
15. Valves stuck or burned; poor seat contact.
16. Stuck pistons or cylinder sleeves.

No Smoke:
1. Emergency shut-off cock closed or partly closed.
2. Fuel tank vent restricted.
3. Fuel supply pump inoperative or leaking.
4. Air leaks or restriction on suction side of fuel system.
5. Fuel filters clogged.
6. Fuel tank or filters cracked; drain plugs loose.
7. Filter air bleed too large or missing; air bleed plugged.
8. Injection pump overflow valve leaky, stuck open or closed.
9. Faulty nozzle spray; leaky; opening pressure incorrect.
10. Nozzle cap nut improperly torqued.
11. Nozzle pintle stuck.
12. Bent or broken spindle or spring.
13. Nozzle improperly installed in cylinder head (binding).
14. Injection pump plunger stuck; pump rack stuck; pump plungers worn.
15. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive assembly; incorrect timing.
16. Improper valve clearance; camshaft or lifters worn.
17. Broken or weak valve springs.
18. Valve guides worn or gummed.
19. Valves stuck or burned; poor seat contact.
20. Leaky cylinder head gasket; leaky gaskets or seals.

Blow-By At Crankcase Breather:
1. Piston rings stuck or worn, broken or improperly fitted.
2. Scuffed pistons or cylinder sleeves.

Engine Stalls Frequently

Low or No Fuel Pressure:
1. Fuel tank vent restricted.
2. Fuel supply pump inoperative or leaking.
3. Air leaks or restriction on suction side of fuel system.
4. Fuel filters clogged.
5. Fuel tank or filters cracked; drain plugs loose.
6. Filter air bleed too large or missing; air bleed plugged.
7. Injection pump overflow valve leaky, stuck open or closed.
8. Air in governor oil feed; insufficient oil pressure (hydraulic governor).

Fuel Pressure Adequate, No Smoke:
1. Improper setting of governor idle speed.
2. Governor throttle shaft linkage binding, or sticky governor parts.
3. Improper setting of governor throttle linkage.
4. Governor drive assembly binding.
5. Broken or weak speeder springs.
6. Solenoid stuck.
7. Improper rack, gap, cam angle or cam plate setting (mechanical governor).
8. Air in governor oil feed; insufficient oil pressure (hydraulic governor).
9. Restriction in lubricating oil system; faulty gauge.
10. Injection pump internal adjustment incorrect; worn injection pump shaft bearings; loose pump drive assembly; incorrect timing.
11. Injection pump plunger stuck; pump rack stuck; pump plungers worn.

Black Smoke:
1. Governor throttle shaft linkage binding or sticky governor parts.

2. Turbocharger passing oil; restricted air intake or clogged air cleaner; nozzle ring restricted, slow charger rpm; binding impeller.
3. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive incorrect timing.
4. Improper valve clearance; worn camshaft or lifters; broken or weak valve springs; valve guides worn or gummed; valves stuck or burned.
5. Faulty nozzle spray, leaky, opening pressure incorrect; nozzle cap nut improperly torqued; nozzle pintle stuck; bent or broken spindle or spring; nozzle improperly installed in cylinder head.

Engine Surges

1. Improper setting of governor idle speed.
2. Air leaks or restriction on suction side of fuel system; fuel filter air bleed too large or missing; air bleed plugged.
3. Air in governor oil feed; insufficient oil pressure (hydraulic governor).
4. Governor throttle shaft linkage binding or sticking governor parts; governor drive binding; broken or weak speeder springs.
5. Loose governor ball-head drive; excess ball-head tang clearance (hydraulic governor).
6. Worn sliding sleeve, flyweight fingers, linkage or excessive end play (mechanical governor).
7. Incorrect speed droop setting, or length of speed follower spring (hydraulic governor).
8. Displaced mechanical governor throttle shaft bushings; yoke binding.
9. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive; incorrect timing.
10. Injection pump plunger stuck; pump rack stuck; pump plungers worn.
11. Restriction in lube oiling system; faulty gauge.

Engine Will Not Attain No-Load Governed RPM

1. Emergency shut-off cock closed or partly closed.
2. Air intake manifold valve closed or partly closed.
3. Fuel tank vent restricted.
4. Low ambient air temperature; use starting aid.
5. Improper setting of governor or high speed stop.
6. Governor throttle shaft linkage binding, or sticky governor parts; improper setting of governor throttle linkage; governor drive binding; broken or weak speeder springs; solenoid stuck.
7. Improper rack, gap, cam angle or cam plate setting (mechanical governor).
8. Worn mechanical governor sliding sleeve, flyweight fingers, worn linkage, excessive end play.
9. Pressure relief valve spring broken or relief valve stuck open (hydraulic governor).
10. Air leaks or restrictions on suction side of fuel system.
11. Fuel filters clogged; fuel tank or filters cracked or drain plugs loose; filter air bleed too large, missing or plugged.
12. Fuel supply pump inoperative or leaking.
13. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive; timing incorrect.
14. Injection pump plunger stuck; pump rack stuck; pump plungers worn.
15. Blow-by at crankcase breather.

Engine Overspeeds

1. Improper setting of governor or high speed stop.
2. Broken mechanical governor throttle spring or linkage disengagement.
3. Governor throttle shaft linkage binding or sticky governor parts; improper setting of governor throttle linkage; governor drive binding; broken or weak speeder springs; solenoid stuck.
4. Injection pump rack stuck.
5. Displaced governor throttle shaft bushings, yoke binding (mechanical governor).
6. Worn mechanical governor sliding sleeve, flyweight fingers, governor linkage, excessive end play.
7. Turbocharger passing oil.

Engine Lacks Power

No Smoke:

1. Emergency shut-off cock closed or partly closed.
2. Air intake manifold valve closed or partly closed.
3. Fuel tank vent restricted.
4. Low ambient air temperature; use starting aid.
5. Air leaks or restriction on suction side of fuel system.
6. Fuel filters clogged; fuel tank or filters cracked, drain plugs loose; filter air bleed too large, missing or plugged.
7. Leaky cylinder head gaskets or seals.
8. Injection pump plunger stuck, pump rack stuck, pump plungers worn.
9. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive; timing incorrect.
10. Improper setting of governor or high speed stop.
11. Governor throttle shaft linkage binding or sticky governor parts; improper setting of governor throttle linkage; governor drive binding; broken or weak speeder springs; solenoid stuck.
12. Incorrect speed droop setting or length of speed follower spring (hydraulic governor).
13. Improper rack, gap, cam angle or cam plate setting (mechanical governor).
14. Air in hydraulic governor oil feed, insufficient oil pressure.
15. Restricted turbocharger air intake, clogged air cleaner; nozzle ring restricted, slow charger rpm; binding turbocharger impeller.

Black or Brown Smoke:

1. Emergency shut-off cock closed or partly closed.
2. Air intake manifold valve closed or partly closed.
3. Fuel tank vent restricted.
4. Low ambient air temperature; use starting aid.
5. Faulty nozzle spray, leaky, opening pressure incorrect; nozzle cap nut improperly torqued; nozzle pintle stuck; bent or broken spindle or spring; nozzle improperly installed in cylinder head (binding).
6. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive; timing incorrect.
7. Improper rack, gap, cam angle or cam plate setting (mechanical governor).
8. Poor engine compression.
9. Improper valve clearance; camshaft or lifters worn; broken or weak valve springs; valve guides worn or gummed; valve stuck or burned; poor valve seat contact.
10. Leaky cylinder head gasket; leaky gaskets or seals.
11. Piston rings stuck or worn, broken or improperly fitted.
12. Scuffed pistons or cylinder sleeves.
13. Restriction in lube oil system or faulty gauge.
14. Turbocharger passing oil; restricted charger air intake or clogged air cleaner; nozzle ring restricted, slow charger rpm; binding charger impeller.

Blue or White Smoke:

1. Leaky cylinder head gasket; leaky gaskets or seals.
2. Piston rings stuck, worn, broken or improperly fitted.
3. Scuffed pistons or cylinder sleeves.
4. Turbocharger passing oil; restricted charger air intake, clogged air cleaner; nozzle ring restricted, slow charger rpm; binding charger impeller.
5. Water leak in combustion chamber, cracked cylinder head.

Engine Won't Shut Down

1. Governor throttle shaft linkage binding or sticky governor parts; solenoid stuck.
2. Incorrect speed droop setting or length of speed follower spring (hydraulic governor).
3. Displaced mechanical governor throttle shaft bushings; yoke binding.
4. Worn mechanical governor linkage, excessive end play.
5. Injection pump plunger stuck; pump rack stuck.

Engine Overheats

1. Leaky cylinder head gasket; leaky gaskets or seals.
2. Turbocharger. Restricted air intake, clogged air cleaner; nozzle ring restricted, slow charger rpm; binding charger impeller.
3. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive, timing incorrect.

Fig. 6 Cylinder head and valve mechanism

4. Nozzle pintle stuck.
5. Improper valve clearance; worn camshaft or lifters; broken or weak valve springs; valve guides worn or gummed; valves stuck or burned.
6. Piston rings stuck, worn, broken or improperly fitted.
7. Turbocharger passing oil; restricted air intake; nozzle ring restricted; charger impeller blinding.

Fuel Consumption Excessive

1. Fuel tank or filters cracked or drain plugs loose.
2. Faulty nozzle spray, leaky, opening pressure incorrect; nozzle cap nut improperly torqued; nozzle pintle stuck; bent or broken spindle or spring; nozzle improperly installed in cylinder head.
3. Leaky cylinder head gasket; leaky gaskets or seals.
4. Poor compression.
5. Improper valve clearance; worn camshaft or lifters; broken or weak valve springs; valve guides worn or gummed; valves stuck or burned.
6. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive; timing incorrect.
7. Injection pump internal adjustment incorrect; worn pump shaft bearings; loose pump drive; timing incorrect.
8. Improper setting of governor or high speed stop.
9. Scuffed pistons or cylinder sleeves.
10. Turbocharger passing oil; restricted air intake; clogged air cleaner; nozzle ring restricted; binding charger impeller.
11. Improper rack, gap, cam angle or cam plate setting (mechanical governor).

Lube Oil Consumption Excessive

1. Clogged crankcase breather or pipe.
2. Leaky cylinder head gasket; leaky gaskets or seals.
3. Turbocharger passing oil.
4. Valve guides worn or gummed.
5. Piston rings stuck, worn, broken or improperly fitted.
6. Scuffed pistons or cylinder sleeves.
7. Blow-by.

Excessive Fuel Pressure

1. Fuel return line plugged or crimped.
2. Injection pump overflow valve leaky, stuck open or closed.

Excessive Oil Pressure

1. Restriction in lube oiling system; faulty gauge.
2. Pressure relief valve stuck closed or faulty oil pump relief valve.

No or Low Oil Pressure

1. Restriction in lube oiling system; faulty gauge.
2. Pressure relief valve stuck closed or faulty oil pump relief valve.
3. Excessive clearance in main or rod bearings.

Low Compression

1. Piston rings stuck, worn, broken or improperly fitted.
2. Scuffed pistons or cylinder sleeves.
3. Blow-by.
4. Leaky cylinder head gasket; leaky gaskets or seals.
5. Improper valve clearance; worn camshaft or lifters; broken or weak valve springs; valve guides worn or gummed; valves stuck or burned.

Crankcase Build-up

1. Blow-by.
2. Leaky cylinder head gasket; leaky gaskets or seals.
3. Piston rings stuck, worn, broken or improperly fitted.
4. Scuffed pistons or cylinder sleeves.

CYLINDER HEAD

Cylinder heads are cast in "threes". Heads should be tightened in the sequence shown in Fig. 1 to 150 lbs. ft. torque. Loosen water and air inlet and exhaust manifolds while tightening. Use new stud nuts at overhaul. Do not use sealing compound on gaskets.

End core hole plugs (large) are 1¾"-18 (used with "O" ring), coat with National Machine Products "Oil and Water Sealer" at assembly. Tap core hole plugs (3.4" pipe) finished flush with head.

ROCKER ARMS

The rocker arm shaft, Fig. 6, is drilled for bottom feed to rocker arms. Install shafts with oil holes down. Rocker arm bracket stud nut torque is 35-40 lbs. ft.

Rocker arm shaft outside diameter is 1.1286" to 1.1291". Bushing inside diameter is 1.1296" to 1.1301". Bushing to shaft clearance should be .0005" to .0015". Rocker arms should not be rebushed locally but exchanged for factory rebushed and ground replacements.

INJECTOR NOZZLE SLEEVE

The sleeve is stainless steel, wet type. The bore in the cylinder head for the large end (A, Fig. 7) of standard sleeve is 1.216" to 1.128". Bore for small end (B) is 1.062" to 1.064". Diameter of standard sleeve at (A) is 1.2205" to 1.2210". Diameter at (B) is 1.0665" to 1.0670". Press fit of sleeve in cylinder head at both (A) and (B) is .0025" to .005" tight.

To remove the sleeve, tap ½" pipe threads in opening and withdraw sleeve with a suitable puller. To install sleeve, heat cylinder head to 180 deg. and apply a suitable oil and water sealer to the sleeve surfaces indicated in Fig. 7 and press into place using a suitable guide.

VALVES

When valves are ground the maximum face run-out should not exceed .0015". Use new or test approved Thompson positive exhaust valve rotators and new keys.

VALVE SEAT INSERTS

Intake and exhaust valve seats are similar except for diameters. Seat width should be $\frac{1}{16}$" to $\frac{3}{32}$". Maximum seat run-out should be .0015". Oversize seats available are .015, .031, .047 and .062 inches. Shrink seat inserts in dry ice and acetone before installing them in cylinder head.

Bore in head for standard intake seat is 2.437" to 2.438". Outside diameter of standard size intake seat is 2.4395" to 2.4405". Press fit of intake seat insert in head is .0015" to .0035" tight.

Bore in head for standard exhaust valve seat insert is 2.082" to 2.083". Outside diameter of standard exhaust seat insert is 2.0845" to 2.0855". Press fit of

Fig. 7 Nozzle sleeve

Fig. 8 Indexing timing gears

exhaust seat insert in head is .0015″ to .0035″.

VALVE SPRINGS

The free length of the inner valve spring is $3\frac{1}{32}$″. Test for 82.1 to 86.4 lbs. when compressed to $2\frac{1}{32}$″. Service limit is 77.2 lbs.

The free length of the outer spring is $3\frac{13}{32}$″. Test for 105.3 to 110.8 lbs. when compressed to $2\frac{5}{32}$″. Service limit is 94.5 lbs.

VALVE GUIDES

Valve guides are installed from deck side of head, relieved end first. Guides should be pressed in the head .0011″ to .0026″ tight. Guides should extend $1\frac{13}{16}$″ from cylinder head deck to face of guide.

Reamed inside diameter of exhaust guide should be .501″ to .502″; for intake guides .4995″ to .5005″.

VALVE LIFTERS

Valve lifters are carbide faced, mushroom type with a nominal lift of $\frac{5}{16}$″. Bore in block for valve lifter is .6865″ to .6890″. Diameter of lifter is .6855″ to .6860″. Clearance of lifter in block is .0005″ to .0035″.

TIMING GEARS

Timing gear backlash is .002″ to .004″. Install gears with mating numbers facing outward. Index dot on large camshaft gear between the two dots on the crankshaft gear, Fig. 8. Index the injection pump and governor drive gear with small camshaft gear, and index auxiliary drive gear with large camshaft gear in the same manner.

A composition front seal is pressed into the timing gear cover. Use centering sleeve when installing cover to assure alignment of seal and crankshaft. Centering sleeve can be made locally to the dimensions shown in Fig. 9.

CAMSHAFT

The camshaft is drop-forged, seven journal, gear driven. Camshaft end play is .008″ to .014″ and is adjusted by thrust button on the gear cover.

To remove and install the camshaft, rotate the crankshaft until the timing dots are toward the top of the engine and in line with the vertical web or crankcase. Crankshaft counterweights will interfere with camshaft if not lined up in this manner.

CAMSHAFT BEARINGS

There are seven pre-sized, steel-backed babbitt bearings used. They are pressed into the case .0025″ to .0055″ tight for Nos. 1 through 6, and .002″ to .004″ tight for No. 7. The inside diameter of the bearings when pressed in place should be 2.441″ to 2.443″ for Nos. 1 through 6 and 2.2535″ to 2.2540″ for No. 7.

Camshaft bearing journal diameters are 2.439″ to 2.440″ for Nos. 1 through 6 and 2.251″ to 2.252″ for No. 7. Journal-to-bearing clearance is .001″ to .004″ for Nos. 1 through 6 and .0015″ to .0035″ for No. 7.

Fig. 9 Dimensions for making timing gear cover centering sleeve

Bearings are available for .015″ undersize camshaft journals. Oil holes in bearings and case of Nos. 1 through 6 bearings must be aligned. Remove burrs after installation of bearings.

AUXILIARY DRIVE

The auxiliary drive shaft, Figs. 10 and 11, is drop forged, two journal, gear driven. A tachometer drive gear is integral with the shaft. The oil pump drive gear and compressor drive is dog keyed to the shaft. The end thrust is taken by a washer pinned to the case and by a thrust button on the timing gear cover. End play should be .008″ to .014″ and is adjusted at the thrust button.

The front auxiliary drive shaft bearing is pre-sized, steel-backed babbitt. When pressed in the case its inside diameter is 2.0635″ to 2.0640″. The front shaft journal diameter is 2.061″ to 2.062″. Journal-to-bearing clearance is .0015″ to .002″.

The rear auxiliary drive shaft bearing is also pre-sized, steel-backed babbitt. When pressed in the case its inside diameter is 2.0005″ to 2.0010″. The front shaft bearing journal diameter is 1.998″ to

Fig. 10 Auxiliary drive for natural breathing engines

Fig. 11 Auxiliary drive for turbocharged engines

Fig. 12 Checking fit of No. 1 piston ring

1.999″. Journal-to-bearing clearance is .0015″ to .003″.

PISTONS

An "F" or arrow is located on piston head to denote front. Formerly, pistons were checked for proper fit by the feeler gauge method which required a 5 to 20 lb. pull to withdraw feeler. Currently the recommedation is to check piston fit with a plug gauge. Proper piston clearance is given in the table.

Oversize pistons available are .001, .002, .003, .020 and .030 inches.

PISTON RINGS

To check the fit of the top ring in the piston, press the ring into the ring groove. When bottomed, the ring face should be flush with or slightly below the groove lands as shown in Fig. 12.

When installing oil rings, extreme care must be taken to avoid bending ring rails. To check oil control rings for proper tension prior to installation, lay ring on a clean surface with equalizer in place. The gap should be as shown in Fig. 13. When installing ring in piston, position butt of equalizer 180 deg. from ring gap.

PISTON PIN

Pin Fit In Rod Bushing—Pin is to be fitted in connecting rod bushing with from .0007″ to .0011″ clearance (.0009″ desired). When installed, split in bushing should be on horizontal axis—never in area of the load.

Pin Fit In Piston Bosses—The fit in piston bosses should be .0001″ tight to .0002″ loose. Pins should be selected to obtain this fit if possible. The fit should be such that after heating the piston in boiling water for two minutes and then quickly trying pin in piston, pin should slide in with a slight push of the thumb.

CYLINDER SLEEVES

These sleeves are Parco-lubrited and should never be honed as this will remove the coating. The outside and inside diameters of these sleeves are held to such figures as to maintain the desired inside diameter when in place.

When installing new sleeves, it is important that the cylinder shoulder recess in the cylinder block be carefully cleaned out after the sleeve has been pressed in to within approximately ¼″ of the shoulder, but before the final seating. Fig. 14 shows cylinder sleeve details.

In servicing the engine it is important to note that out-of-round or taper of bore does not exceed the maximum of .002″. If necessary, rebore cylinder for a sleeve of .012″ oversize. Sleeve press fit in the cylinder should be from .000″ to .002″ tight. Dry ice should be used to shrink the sleeve.

Cylinder bore may be honed if necessary to get proper fit of sleeve *but sleeve must never be honed.*

Fig. 13 Checking tension of oil control piston rings

Fig. 15 Connecting rod bearing fit

Fig. 14 Cylinder sleeve shoulder detail

CYLINDER BLOCK

The block is chrome-nickel alloy with dry liners (sleeves). The flywheel housing to block screw torque is 140 lbs. ft. Deck area under each cylinder head should be flat within .0015″. Excessively eroded water transfer ports must be built up to gasket hole size.

CONNECTING RODS

The nominal length between rod centers is 11.250″. Cap angle is 35 deg. The word "Front" is embossed on the rod web. Rods are classified by weight; part numbers of all rods in each engine must have same "P" number suffix (weight classification).

Do not interchange rod caps. Rod and cap thrust faces must be flush when assembled. Use new screws on rods having over 50,000 miles of service.

ROD BUSHING

A split bronze bushing is used. Free outside diameter push fit when bore is 1.6940″; "no go" in 1.6925″ bore. Connecting rod bore for bushing is 1.6875″ to 1.6885″. See *Piston Pin* for fit in bushing. Bushing hole must be aligned in rod.

ROD BEARINGS

These bearings are precision type with locking tongues, steel-backed, copper lead. Bearing crush fit in rod cap is .002″ to .003″ with 18 lbs. ft. torque on cap screw, Fig. 15.

The inside diameter of bearings in place is 2.9991″ to 3.0006″. Crankpin diameter is 2.9975″ to 2.9980″. Bearing-to-crankpin running clearance is .0011″ to .0031″ with 150 lbs. ft. torque on cap screws.

Available undersizes are .002, .010, .020, .030, .040, .050 and .060 inches.

Fig. 16 Sectional view of water pump

MAIN BEARINGS

Seven precision type, steel-backed, copper lead with babbitt overlay bearings are used. The case bore for the bearings is 4.251″ to 4.252″. Bearing crush fit is .001″ to .002″ with 15 lbs ft. screw tension for bearing Nos. 2, 3, 5, and 6; 18 lbs. ft. for No. 1, and 12 lbs. ft. for Nos. 4 and 7.

When in place the inside diameter of bearings is 4.0010″ to 4.0030″. Main bearing journal diameters and running clearance are listed in the bearing table.

Available undersize service bearings are .002, .010, .020, .030, .040, .050, .060 inches.

Crankshaft end thrust is taken on No. 4 bearing by thrust washers. End play is .004″ to .011″ and is obtained by thrust washer selection. Thrust washer thicknesses are .090″ to .091″, .092″ to .093″ and .102″ to .103″.

Do not interchange main bearing caps. Be sure No. 4 case and cap thrust faces are flush when installed.

CRANKSHAFT

Maximum journal out-of-round or taper of crankshaft journals is .0015″. Maximum run-out at No. 4 bearing journal with Nos. 1 and 7 main journals supported in V blocks is .0015″.

Flywheel bolt press fit in flange should be .0005″ to .002″ tight. Vibration damper-to-hub capscrew torque is 43 lbs. ft.

When main journals are reground, fillets are sized to .150″ to .170″ and polished with No. 240 sandcloth.

CRANKSHAFT REAR OIL SEAL

The lead wire crankshaft rear oil seal is carried by a bolt-on oil slinger housing. The butt joint of the seal must be toward the top of the engine to assure oil control. Use a smooth wooden dowel to roll the seal in place.

LUBE OIL PUMP

The pump is the gear type driven by the auxiliary shaft. Gear-to-housing side clearance is .005″ to .009″. Gear-to-housing end clearance is .0015″ to .002″. Gear backlash is .027″ maximum. Relief valve spring free length is 3⅝″; test 25 lbs. at 2¾″.

Fig. 18 Sectional view of synchrovance

Fig. 17 Schematic diagram of Mack diesel fuel system

WATER PUMP

The water pump, Fig. 16, is belt-driven by the crankshaft. The pump shaft is supported by two ball bearings, lubricated by ball and roller bearing grease by grease cup.

Stationary carbon seal bears against rotor hub. Seal extension beyond cover boss is $\frac{5}{16}$″. Rotor blade-to-cover clearance is .030″ by location of pin hole in rotor. Use shaft hole as a jig when drilling $\frac{3}{16}$″ hole in new rotor. Slinger-to-outer bearing race clearance is .005″ to .007″ as indicated.

FUEL SYSTEM

The fuel system, Fig. 17, is the heart of the diesel engine. It serves to filter the fuel, meter the amount injected into the combustion chamber and inject it at the proper time to obtain peak performance.

All Mack naturally-aspirated engines are fitted with a synchrovance unit which advances the injection timing throughout the speed range.

Due to the combustion characteristics of a turbocharged engine, the injection timing is confined to a much narrower range and a fixed coupling provides satisfactory results.

A governor, either mechanical or hydraulic depending upon the engine model, provides a coupling between the accelerator linkage and the injection pump rack, thereby regulating fuel delivery in response to pedal position, load and engine speed.

Service Hints

Servicing of all units of the fuel system depends upon operating conditions and type of fuel used.

Injection Nozzles— Remove, test opening pressure and check spray pattern, *but only if trouble is indicated.* Observe for leakage from bleed line connections and nozzle cap nut. Both hold-down nuts should be tightened evenly to prevent binding internal parts.

High Pressure Fuel Lines—These lines

Fig. 19 Disassembled view of synchrovance assembly which is used on natural breathing engines only

are seamless, cold-drawn, high tensile steel. All six lines are of identical length and inside diameter. Replacement lines must be identical in design to avoid serious impairment of injection characteristics. When servicing engine, inspect all fuel line brackets for proper tightness to prevent chafing of lines which might cause eventual line leakage.

Initial Fuel Filter (When Used)—Remove center shaft cap nut and turn shaft two complete revolutions. Remove drain plug to let out sediment and water. Turn handle more frequently during extremely cold weather.

Fuel Filter—Filter element should be changed if fuel pressure (checked with engine running) drops below 3 lbs.

Constant Air Bleed (When Used)—The fuel piping is so arranged to provide a continuous air bleed line between the filter and injection pump gallery return line. Whenever the filter has been opened or a low pressure line disconnected, this line will automatically bleed the system when the hand priming pump is operated.

If a constant air bleed line is not installed, an air bleed fitting will be found on top of the filter. After installing a new element, open the air bleed and operate the hand priming pump until all air and foam are expelled from the filter body.

Fuel Pressure Gauge (When Used)—This gauge is installed in the fuel pressure line feeding the pump gallery. With the engine running under normal conditions the fuel pressure will be 12 to 15 lbs.

Pressure Gauge Shut-Off (When Used)—This cock is opened for checking fuel pressure and closed after reading is noted.

Hand Priming Pump—Operate the pump to bleed air from the low pressure system whenever a filter has been opened or a line disconnected; and also when making port closing test.

Fuel Tank—Drain off the water and sediment periodically. Fill tank before standover. Be sure fuel is absolutely clean and of proper specifications. When vehicle is to be operated in extremely cold weather, mix kerosene with fuel in proper proportion to obtain a pour pint 10 deg. below lowest expected temperature.

SYNCHROVANCE

This device, Figs. 18 and 19, provides a variable-angle coupling between the injection pump and the injection pump drive. It automatically advances the injection timing of the injection pump beyond the static setting as the engine speed increases so that, throughout the entire speed range, injection occurs precisely at the moment required for maximum performance.

The synchrovance is a matched, non-adjustable, calibrated unit, and parts are not interchangeable. Service is by replacement with a calibrated exchange assembly.

Fig. 20 Hydraulic governor internal adjustments

Removal and Installation

With injection pump removed from engine, loosen the coupling screw and remove coupling nut. Slide coupling, springs, spring spacers, collar and thrust washer off spider as an assembly. Position a suitable puller over the spider so that puller pins enter the two radial holes in the exposed portion of spider. Steady puller bridge with a suitable wrench and turn puller screw clockwise until spider breaks free.

To install, position key in key slot of injection pump tapered shaft and slide synchrovance into position. Place coupling washer on coupling nut and screw nut down tight. Tighten coupling screw to lock in place.

HYDRAULIC GOVERNOR

Governor action provides a coupling between the accelerator linkage and injection pump rack that regulates fuel delivery in response to pedal position, load and engine speed. Hydraulic pressure, developed by a self-contained gear pump, acts on a servo piston to move the rack. Oil flow to and from servo piston is controlled by a pair of spring-loaded flyweights (loading varied by pedal movement) which position a spool type pilot valve.

Internal Adjustments

Referring to Fig. 20, make adjustments with engine warm and running.

To make the droop screw adjustment, if the engine tends to "hunt", especially after a sudden throttle change, remove cover and turn droop screw *in* until engine just holds speed without hunting.

To make high speed adjustment, loosen high speed screw lock nut and hold speed adjusting lever against screw. Turn screw *in* to decrease or *out* to increase speed. Tighten lock nut and replace cover.

To adjust idle speed, have cover in place and adjust idle screw to obtain 500 rpm and lock in place.

Linkage Adjustments

Fig. 21. With throttle yoke (A) disconnected, set throttle link idle stop screw (B) with 1¼" dimension between screw crown and rear of boss and lock with jam nut. Hold link against screw crown, loosen lever screw (C) and, with governor speed adjusting lever (D) against governor idle stop screw (E), position throttle linkage lever (F) on speed adjusting shaft (G) so the $\frac{1}{16}$" dimension shown is obtained. Check clearance with a $\frac{1}{16}$" wire at lower end of slot. Tighten screw (C).

Fig. 22. Rotate lever (F) clockwise until lever (D) contacts high speed stop screw (H). Then set stop screw (J) so that it just touches link (K). Lock screw with jam nut. Connect yoke (A) to link (K) and adjust stop screw under accelerator pedal so that pedal movement is stopped when link (K) contacts screw (J).

Be sure slot in shut-down shaft (L) is vertical when lever (M) is in running position. Reposition lever if necessary. Check operation of this control.

Fig. 21 Hydraulic governor linkage adjustments

Governor Gaskets

The gasket under the hydraulic governor and the gasket under its dust shield should be installed *dry* without use of shellac, cement or sealing compound. These materials, when used on the gasket, has been found to work into the governor and cause sticking of the pilot valve, servo piston and other moving parts, necessitating a reconditioning of the unit. In the case of the dust shield gasket, the compound runs directly into the servo piston.

The result of a sticking governor can be engine runaway and serious damage.

Droop Screw Looseness

The droop screw should be a snug fit in the torque control cam, Fig. 23. Should this screw fall out it would hold the servo piston in an open position.

Whenever the cover of a governor is removed for adjustment, check the droop screw for snugness with a suitable wrench. There should be a definite bind or resistance to turning.

If the screw is loose, tip the cam up so that the slot can be either spread open with a small screwdriver or pinched to close the gap with a pair of pliers. Use care to avoid breaking the cam.

The cam may be tipped sufficiently to perform this operation without removing it from the engine or dismantling.

FUEL INJECTION PUMP

Timing Pump to Engine

This procedure is outlined at the beginning of this chapter under *Tune Up.*

Pump Service

No service is required on the pump between major overhauls except the breather cap must be cleaned. When service is required, it must be performed by an American Bosch or Mack Authorized Service Agency.

Pump Adjustment

The only "adjustment" possible to the pump proper is made by adjusting the control rack setting to change the fuel delivered at full load and thus provide a change in engine output. In general this setting is established by the factory for the specific engine and should not be altered. In some cases, a change is permissible but should not be attempted without consulting an authorized Mack Service Agency.

In the event that a part load or low idle "miss" is encountered, or a sound similar to a connecting rod bearing knock or a piston pin knock is heard, the relation between the gear segment and the control sleeve should be checked. A line is inscribed in alignment between each segment and the control sleeve, following calibration. If any scribed lines are found to be out of alignment, loosen the gear segment clamping screw, reposition the control sleeve and retighten the gear segment clamping screw securely. This should only be done by an authorized Mack or American Bosch service station.

Misalignment of the scribed lines indicates the original setting has been disturbed and will result in the various cylinders receiving an unequal charge of fuel.

MECHANICAL GOVERNOR

The mechanical governor is a centrifugal unit mounted directly on the injection pump housing opposite the drive end. The prime purpose of the governor is to serve as a means of presetting and maintaining within close limits any desired engine speed with the nominal idling and maximum speed range, irrespective of engine load. In addition, the governor controls the engine idling speed to prevent stalling and the maximum speed to prevent racing.

The governor is driven by a gear mounted on the injection pump camshaft extending into the governor housing and engages a smaller driven gear mounted on the governor shaft. A torsion absorbing member is built into the drive gear to dampen torsional vibrations in the pump camshaft and drive for the protection of the governor components.

Fig. 22 Hydraulic governor linkage adjustments

Fig. 23 Remedy for droop screw looseness on hydraulic governor

No service is required on the governor except the breather cap must be cleaned. Lubrication is automatically controlled from the injection pump housing.

Adjustment

Changes in engine speed should only be made when necessary to conform with speeds given in the Mack Operating Manual. The adjustments are originally set and sealed by the Mack Company.

The nominal engine idling speed and full load speed may be determined from the stamping on the governor name plate—for example GVB 250/1050C. The 250 indicates that the nominal idle governor speed is 250 rpm (500 rmp engine speed because the pump and governor are driven at one-half engine speed). The 1050 rpm or 2150 rpm is the nominal maximum engine speed under full rated load. When the engine is under no load, the speed will increase above this governed figure to what is termed a high idle speed (also known as no-load governor speed). This speed is shown in Mack Operating Manual which goes with the truck.

Before attempting to make governor adjustments warm up the engine thoroughly.

High Speed Adjustment

Fig. 24 illustrates a governor being adjusted for high idle speed. The operating lever in this case at the rear of the pump (not shown) has moved toward the full load position until the stop plate on the lever shaft has contacted the high speed adjusting screw. This screw is always the one nearest to the injection pump.

When the engine reaches its maximum speed, check by means of a tachometer whether or not this is the high idling speed specified in your instruction manual. If the speed is too low, raise the high speed adjusting screw and, if the speed is too high, lower the screw. After the

correct speed is obtained, secure the adjusting screw by means of a lock nut and recheck the speed, making sure that the stop plate on the governor operating lever shaft is in contact with the adjusting screw.

These governors are equipped with a shut-off lever at the top of the governor housing adapter as shown in Fig. 24.

Idle Speed Adjustment

To make this adjustment, Fig. 25, move the operating lever in the direction of less speed until the engine reaches the correct idle speed. Hold the operating lever in this position and screw in the idling adjustment screw until its lower end touches the stop plate on the operating lever shaft.

Service Note

The nominal idling and maximum speeds controlled by the governor cannot be varied to any great extent because they depend entirely upon the characteristics of the spring combination contained in the governor unit. If the governor adjustments are not sufficient to obtain the desired speed a Mack authorized service agency should be consulted for assistance in obtaining the required governor spring combination.

Fig. 24 High speed adjustment on mechanical governor

FUEL SUPPLY PUMP

The fuel supply pump draws fuel oil from the fuel tank of the vehicle and pumps it through the fuel filtering system into the injection pump. The pump is mounted directly on the housing of the injection pump and is driven by a cam on the injection pump camshaft. It is a self-regulating, plunger type pump which will build up pressure only to a predetermined point. The self-regulating feature is a safety device and is normally not called upon in regular operation. The pump is prevented from reaching its self-regulating pressure by an overflow valve located on one end of the fuel injection pump housing. This overflow valve maintains a pressure of approximately 15 psi in the injection pump fuel sump which is considerably below the self-regulating pressure of the supply pump. Fig. 26 is an exploded view of this unit.

Service

Difficulties with the fuel supply system, often blamed on the supply pump, may sometimes be traced to such causes as clogged filters, or air leaks on the suction side fittings. Dented, badly crimped or spongy supply lines cause severe fuel flow restrictions. Dirt or scale may lodge under the supply pump valves. This can readily be checked by removing the spring retaining nut and hand primer adapter to permit examination of the valves and their seats in the pump housing, Fig. 26.

If doubt still exists after this examination a 0 to 30 psi gauge can be installed

Fig. 27 Fuel nozzle and holder assembly

Fig. 26 Exploded view of fuel supply pump and hand primer assembly

at the fuel inlet of the injection pump. With the engine running, this reading should be approximately 15 psi, although satisfactory operation can be obtained at a minimum of 3 psi. If the pressure is within specified limits at this take-off point, the supply pump is satisfactory.

FUEL NOZZLE & HOLDER

The nozzle and nozzle holder, Fig. 27, is utilized to carry the high pressure fuel through the cylinder head to the combustion chamber and deliver it in the form of a fine spray through four equally spaced holes in the nozzle tip.

Service

It is very important that the injection nozzles work at peak efficiency. Generally speaking, it is wise to leave the nozzles alone in engines which are operating satisfactorily, as to disturb them only invites trouble, especially if the work is not done expertly. Any signs of engine miss or loss of power, however, suggests checking of the nozzles after all other conditions have been verified. In checking nozzles, carefully observe the following:

1. Extreme cleanliness is essential.
2. Clean the engine head especially around the nozzle holders before removing the holder and nozzle assemblies to prevent the entrance of dirt into the engine.
3. Test the nozzle and holder assemblies with a test stand for nozzle leakage, opening pressure and spray pattern. The nozzle must open between 2300 and 2350 psi. Check the spray pattern for four equal length sprays having no coarse stringers. *Relieve all nozzle spring tension before disassembling the nozzle from the holder to avoid damaging the nozzle locating dowel pins.*
4. If necessary, after the nozzle has been disassembled from the holder, clean the spray holes with the special cleaning needle held in a pin vise. Practice extreme care so as *not to break off the needle in the spray holes.*
5. Relieve all nozzle spring tension before assembling the nozzle to the nozzle holder to avoid damaging the nozzle dowel pins. The two dowel pins on the holder must be carefully aligned with the holes in the nozzle to insure the proper positioning of the spray holes.
6. Recheck the nozzle and holder assembly. If the performance is unsatisfactory, consult an Authorized Mack Service Agency for repairs.
7. Ream the carbon from the nozzle holder engine port. Use the reamer lightly, just enough to remove the carbon. A special brush (obtainable from Mack) should be used to clean the inner bore.
8. Always use a new nozzle cap nut gasket.
9. Slide the neoprene water sealing gasket on the nozzle and holder assembly in the engine.
10. Tighten the stud nuts to 168-204 inch lbs. (14-17 ft. lbs.) Tighten nuts evenly and do not exceed this torque.

Fig. 25 Idle speed adjustment on mechanical governor

Fig. 28 Water-cooled turbocharger (5″ Series). Currently used 4″ Series is oil cooled

TURBOCHARGER

This unit, Fig. 28, is essentially an exhaust driven blower or air compressor. Its purpose is to increase the air supply to the cylinders over that of a naturally aspirated engine. This increased supply of air allows the engine to burn more fuel, which in turn produces more power, and incidentally results in cooler engine operation.

The turbocharger consists of the following main parts: the turbine, the bearing housing, and the compressor. The turbine is located at one end of the bearing housing, the compressor at the other end. A shaft connects the turbine wheel with the compressor wheel, making it a wheel assembly. The wheels are also referred to as impellers or rotors.

The turbine makes use of some of the heat energy normally thrown out in the exhaust gas. The exhaust gas from the engine enters the turbine housing through the flange connection of the housing. The gas flows around the turbine housing and radially inward through a set of nozzles. These nozzles give the gas a high velocity before it enters the turbine wheel.

The exhaust gas pressure is converted into kinetic energy which acts upon and drives the turbine wheel. The turbine wheel in turn drives the compressor wheel which is basically a vane type centrifugal blower.

The air enters at the center of the compressor wheel and flows radially outward through a diffuser section into the compressor housing. The air leaves through a tangential outlet on the out-

side of the compressor housing and enters the intake manifold.

The Series 5 turbocharger, shown in Fig. 28, has a water-cooled bearing housing. Engine cooling water is circulated through the housing which keeps the bearing area cool and also acts as a heat barrier between the hot turbine and the compressor.

On all model 3 and 4 series, cooling is accomplished by engine oil circulating through the bearing housing.

Piston ring type oil seals are used at each end of the shaft with air pressure from the compressor directed behind the rings to effectively seal off oil. A radial hole in the compressor housing connects with an axial hole in the bearing housing from which short radial holes lead to the shaft near the ends.

Maintenance

The turbocharger is a high-speed (about 48,000 rpm at 2100 rpm engine speed) precision-built mechanism. When it requires repair, it is to be exchanged with a factory rebuilt unit, obtainable from Mack service stations. *No attempt should be made to disassemble the unit for repair.*

Maintenance consists mainly in cleaning and clearance checks as given below.

Cleaning

The blower end of the turbocharger should be cleaned after 1000 to 2000 h .rs of operation. If the impeller is not too dirty, it can be cleaned with the turbocharger on the engine.

1. Disconnect blower discharge flange. Remove capscrews that hold blower casing to intermediate casing and pull blower casing carefully along the turbocharger axis to prevent damage to the impeller or diffuser.
2. Use Bendix cleaner or some similar solvent, *but never use a caustic solution or any other type that may attack aluminum,* as this will either weaken the impeller or destroy its balance. *Never use a wire brush or scraper*—a brush with nylon or hog bristles is preferable.
3. If the unit is found to be very dirty when the blower casing is removed, remove the turbocharger from the engine for cleaning. With blower casing removed, immerse the impeller end of the turbocharger into the cleaning fluid *up to the edge of the intermediate casing* and allow it to soak. Use care not to rest the weight of the turbocharger on the impeller or on the end of the shaft.
4. At each cleaning, the turbine wheel cooling air holes from the back of the diffuser through the intermediate casing must be cleaned. This can be done by passing a wire through the holes and then using air pressure to blow out loose particles.

Clearance Checks

The clearance shown in Fig. 28 should be checked every 3000 hours of operation. The bearing housing assembly with rotors should be separated from the end housings to make this check. Do not disassemble the bearing housing assembly.

It is not possible to measure seal clearance without removing rotor, but there will be no seal wear unless there is bearing wear. If the clearances indicated in Fig. 28 are excessive, the assembly should be exchanged for a factory rebuilt unit.

①—Latest production.
②—Intake 30°, exhaust 45°.
③—Flywheel and vibration damper.
④—Short studs 100 lb. ft.
⑤—If engine has Invar push rods, clearance is .015″ cold.
⑥—With 7.5 compression ratio.
⑦—With 6.7 compression ratio.
⑧—Using "Clearomatic" pistons.
⑨—Using "Trunk Type" pistons.
⑩—Outer spring.
⑪—Special service head, spark plugs on left side, washer necessary to locate exhaust valve rocker arm.
⑫—Disregard instruction plate on manifold which gives .012 intake and .025 exhaust. Mack suggests replacing instruction plate.
⑬—The 402 engine is identical to the 401 except that the 402 has 34 cylinder head studs instead of 32.
⑭—With "Clearomatic" pistons 11°, with "Trunk" type pistons 13°.
⑮—Champion. Normal service.

Engine Section

CYLINDER HEAD, REPLACE

All Engines

When removing a cylinder head a chisel or screw driver should never be used to pry it loose from the cylinder block. On L-head engines, use an eyebolt in the third or fourth spark plug hole, lifting up on the eyebolt while tapping lightly around the edges of the head with a lead or rawhide hammer or mallet. Be sure that all the head stud nuts or bolts have been removed before starting to remove the head.

In replacing the head, the stud nuts or bolts at the center of the head should be tightened first and then work outward from side to side and to the ends, Figs. 1, 2 and 3.

Draw the nuts or bolts down evenly until all are normally tight. Then after the engine has run long enough to warm it up, make a final tightening with a torque wrench to the torque loads given in the *Tune Up & Valve Specifications* table.

On overhead valve engines, be sure to check the valve clearances after the final tightening.

Fig. 1 Cylinder head tightening sequence. 431, 438, 464, 540 engines

Fig. 2 Cylinder head tightening sequence. 707 engines

Section through EN-431A and 464 engines at piston and intake valve

ROCKER ARM SERVICE

Overhead Valve Engines

Sludge and gum formation in the rocker arms and shafts will restrict the normal flow of oil to the rocker arms and valves. Each time the rocker arm and shaft assemblies are removed, they should be disassembled and thoroughly cleaned.

When disassembling rocker arms, place all parts on the work bench in their proper sequence to insure correct assembly.

Clean all gum and sludge formation from the inside and outside of the shafts. Clean oil holes and passages in the rocker arms and shafts. Clean the oil connector. Inspect the shafts for wear.

Check the ball ends of the rocker arms to be sure they are not pitted or rough. If used in this condition, it will be difficult to mantain valve clearances.

VALVES, ADJUST

All Engines

Adjust the valves to the clearances given in the *Tune Up & Valve Specifications* table. If the valves are to be adjusted warm, run the engine for about 30 minutes to normalize the expansion of all parts.

On overhead valve engines, be sure the cylinder head is properly tightened down before adjusting valve clearances.

VALVES, REMOVE

L-Head Engines

After taking off the cylinder head, remove the valve chamber covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until

Fig. 3 Cylinder head tightening sequence. EN-291, 331 and 401 engines. The 402 engine has 34 studs

Section through EN-291, 331, 401 engines at intake valve

those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so that they can be identified as to the valve port from which they were removed.

Overhead Valve Engines

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

VALVES, GRIND

All Engines

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum amount of metal required to clean up the vlave faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}$", otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the block or head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing has a valve guide pilot.

The valve seat width after refacing should be $\frac{5}{64}$" to $\frac{7}{64}$" on the intake. The width of exhaust seats should be $\frac{7}{64}$".

A simple check can be made to prove the fit of the valve in the valve seat by spreading a thin film of Prussian Blue on the valve face and inserting the valve in the valve seat. With hand pressure, rotate the valve ¼ turn, remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer will indicate an inaccurate valve and valve seat operation.

VALVE SEAT INSERTS

All Engines

Since these inserts are too hard to reface by the ordinary hand grinding method, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and the valve guide pilot is a snug fit in order to assure a concentric finish. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert (if a suitable puller is not available), drill two holes at opposite sides of the insert but not all the way through. Then cut out the undrilled portion with a sharp chisel and remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the new insert with "dry ice" to obtain maximum contraction of the metal and place it in the recess. If necessary, the insert may be pounded in by using a round driver the same size as the insert and pounding on same with a hammer.

If a standard insert is too loose, secure an oversize insert. Of course, the recess should be bored out to accommodate the oversize insert.

When installed, peen the block or head around the insert bore to insure the insert remains in place.

VALVE SPRINGS

After removing the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. If not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Tune Up & Valve Specifications* table within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should be scrapped.

VALVE GUIDES, REPLACE

Clean the valve guides with a wire guide brush and check the clearance between valve stems and guides. Excessive clearance will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Valve stem-to-guide clearance may be checked with a dial indicator or a suitable plug gauge. Lacking either of these tools, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check indicates excessive clearance, it will be necessary to replace the valve guide.

If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

Valve guides may be removed and installed with a suitable puller and installer made for the purpose. If such equipment is not available, the old guides can be driven out or they can be pulled out by using a piece of pipe together with a long bolt and suitable washers.

After the new guides have been installed, they should be reamed to round out the holes and to provide adequate operating clearances.

VALVE LIFTERS

All Engines

On some engines, valve lifters are of the barrel type, operating in guide holes bored in the cylinder block. To remove lifters of this type, take off the engine side cover and take out the lifters.

Other engines have valve lifters which operate in removable guide clusters bolted to the cylinder block. To remove lifters of this type, merely unbolt the guide clusters from the block and take out the assembly.

Another design is where the lifters operate in bushings pressed in the block. These bushings may be pressed out after the lifters have been removed. After pressing in the new bushings, they should be reamed to provide the proper operating clearance and to eliminate any distortion which may have occurred during the replacement operation.

TIMING GEARS

All Engines

If the timing gears are removed for any reason, the camshaft must be timed when the gears are replaced. Before removing gears, make sure the timing marks are legible. And when replaced, valve timing will be correct if the marks on the camshaft and crankshaft gears are meshed.

CAMSHAFT & BEARINGS

All Engines

Camshaft bearings should be installed in sets and care must be exercised to see that the oil holes in the bearings are aligned with the oil feed holes in the block to assure adequate lubrication.

To assure proper camshaft fit on engines with crankcase separate from the cylinder block, line-ream camshaft bearings after the block is bolted in place.

PISTONS & RODS, REMOVE

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Before removing pistons, mark the pistons with a file on the inside of the skirt to indicate the bore from which each piston was removed and also its position in the bore with relation to the camshaft side of the engine. Connecting rods should also be suitably marked if they are not marked already.

Remove the connecting rod caps and push the assemblies out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. It is advisable to install caps on rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

All Engines

If the pistons and rods have factory markings to indicate their position in the cylinders, assemble and install them according to these marks, or according to the marks made during removal if they were not otherwise marked.

PISTONS, REPLACE

All Engines

Before a honing or boring operation is started, measure all new pistons with a micrometer at points 90° away from the piston pin. Then select the smallest piston for the first fitting. The slight variations usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

PISTON RINGS, REPLACE

All Engines

When new rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the diameter of the bore. This is done with a "Glazebuster" or a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is be fitted. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

PISTON PINS, REPLACE

All Engines

In some engines, the pins are clamped in the rod, and when installing pins of this type, turn the notch in the pin to line up with the clamp screw hole in the rod to prevent damage to the clamp screw threads as it is being installed.

In other engines, the pins are of the floating type, being free to rotate in both the rod and piston bosses. These pins are prevented from rubbing against the cylinder wall by either snap rings which fit in grooves in the piston bosses, or by aluminum plugs pressed in the ends of the pins.

Pins should be selected that can be installed by pushing with the palm of the hand with piston at normal room temperature. To make assembly easier, however, heat the piston in boiling water for a few minutes to obtain maximum expansion of the metal and quickly insert the pin.

Fig. 4 Crankshaft rear oil seal. All Engines

ROD BEARINGS, REPLACE

All Engines

Rod bearings consist of two half shells. When the bearings are placed in the rod and cap the ends extend slightly beyond the parting faces so that when the rod bolts are tightened, the bearings will be clamped tightly in place to insure positive seating and prevent turning. *The ends of these bearings should never be filed flush with the parting surface of the rod and cap for the above reasons.*

Service bearings are provided in standard sizes and several undersizes, including undersizes for reground crankshafts.

After installing new bearings, the oil clearance may be checked with Plastigage which is readily available at any auto parts jobber. Full instructions for its use are furnished with the envelope in which it is contained.

MAIN BEARINGS, REPLACE

All Engines

Main bearings are of the insert type, requiring no reaming or scraping. They may be removed and replaced without removing the crankshaft.

Plastigage may be used to check bearing clearance and instructions for its use are contained in the package.

CRANKSHAFT END PLAY, ADJUST

All Engines

Through normal wear, crankshaft end play will seldom become excessive but whenever new bearings are fitted check the end play carefully and correct as required.

End thrust is controlled by thrust washers at the center main bearing. If end play is excessive, install new washers.

CRANKSHAFT OIL SEAL

All Engines

An oil slinger, integral with the crankshaft, behind the rear main bearing, and a lead seal inserted in the flywheel housing at the rear of the slinger, Fig. 4, prevents oil leaking at this point.

OIL PUMP REPAIRS

All Engines

Conventional gear type oil pumps, located in the crankcase, are used on all engines. After removing the oil pan, the pump may be unfastened from its mounting and disassembled for repairs.

Inspect the pump gears for nicks or burrs. Inspect the bottom cover for wear and dress it down on a surface plate with emery if necessary. Place the cover on the pump and check the drive shaft end play. If end play is in excess of .006", replace the drive and idler gears.

WATER PUMP REPAIRS

All Engines

The water pumps used on these engines are of the ball bearing type with sealing accomplished by a non-adjustable spring-loaded seal, Figs. 5 and 6. In servicing these pumps, note carefully the arrange-

Fig. 5 Typical sealed type ball bearing water pump on engines using one fan belt

ment of the seal parts as they are removed so that the new seal may be assembled correctly.

IGNITION TIMING

All Engines

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

HOLLEY CARBURETORS

AA-1G & 885-JJS

These carburetors, Figs. 7 and 8, are dual downdraft units incorporating an integral governor. The governor throttle mechanism is part of the carburetor and has been designed to provide the needed power required for moving the throttle to governing speeds as controlled by a separately driven governor rotor. The combination of these two units give instant response and accurate governing.

Fuel & Float Level

When checking the fuel level in an open vessel, under 3 lbs. pump pressure the level should measure $\frac{19}{32}$" on AA-1G models and $\frac{5}{8}$" on 885-JJS units. The measurement is taken below the surface of the float chamber cover (gasket in place) to the level of the fuel. The

Fig. 11 Zenith carburetor float settings

Fig. 8 Holley 885-JJS carburetor

Fig. 10 Zenith 28 Series carburetor

level may be corrected by bending the float arm.

The float level can be set when the air horn is off by gauging the distance between the bottom of the float and the flange surface of the air horn, Fig. 9. Holding the air horn upside down and the float in the closed position, measure the distance from the flange surface of the air horn to what would normally be the bottom side of the float (not the soldered seam). The correct distance should measure 1¼" on AA-1G and 1⅜" on 885-JJS. Bend the float lever arm as required to correct the float level.

Fig. 13 Zenith 63 Series carburetor

Fig. 12 Zenith 29 Series carburetor

Idle Mixture

The idle mixture is controlled by the idle adjustment needles. Turning these needles in makes a leaner mixture and turning them out makes the mixture richer. Turn the needles in until they just touch the seats and back off one full turn.

When the engine has warmed up to operating temperature, alter the adjustment as required to obtain smooth performance. The range should be between 1 and 1½ turns.

Accelerating Pump

The quantity of the fuel discharged by the accelerating pump can be controlled by changing the position of the pump link in the throttle lever. Of the three different positions (marked 1, 2 and 3) number 2 is the average setting, number 1 is for summer and 3 is for winter operation.

Fig. 15 Holley carburetor governor. Model 1174

ZENITH CARBURETORS

28ADA10

This carburetor, Fig. 10, is a downdraft, single-barrel unit with a mechanically-operated accelerating pump and a manifold vacuum controlled power jet system.

Float Setting

Float height setting is measured from the gasket surface or parting line of the float chamber cover to the bottom of the float at the center, Fig. 11, with the fuel inlet valve seated (holding float chamber cover upside down). This distance should measure 1½".

Under three pounds fuel pump pressure the fuel level should measure $\frac{25}{32}$".

Idle Mixture

For a preliminary adjustment, turn the idle adjusting needle into its seat and open one full turn. Run the engine until it reaches normal operating temperature and alter the adjustment as required to obtain smooth performance. The range should be between 1 and 1½ turns open.

Accelerator Pump

The accelerating jet and the pump spring control the rate of acceleration discharge. The stroke of the pump is controlled by the position of the pump rod in relation to the pump piston rod. The stroke can be varied by changing the position of the hairpin clip on the pump piston rod. The upper groove allows a half stroke. The center groove allows an intermediate or ¾ stroke and the lower groove allows maximum or full stroke.

29D13 & 14

This carburetor, Fig. 12, is a downdraft carburetor with a concentric float bowl. This design assists in the proper metering of the air and fuel to the engine without flooding when the vehicle is operated at extreme angles. The fuel chamber can be tipped at an angle to any position within a circle up to 45°. This feature is very helpful when the vehicle is operated in hilly country, in and out of excavations, on ramps, or when operated at side angles.

Float Setting

With the cover and float assembly held upside down and fuel inlet needle held closed, the distance indicated in Fig. 11 should be $1\frac{41}{64}$".

Idle Mixture

For a preliminary adjustment, turn the needle into its seat and open one full turn. Run the engine until it reaches normal operating temperature and alter the adjustment as required to obtain smooth performance. The range should be 1 to 1½ turns open.

Zenith 63 Series

Zenith 63AW-12, 63AW-14 and 63AW-16 models are used on these engines, Fig. 13. They are single barrel, updraft carburetors with a manifold vacuum-controlled power and accelerating system. A removable venturi tube measures the volume of air which passes through the carburetor.

Float Setting

Float height setting is measured from the gasket surface or parting line of the float chamber cover to the bottom of the float at the center, Fig. 11, with the fuel inlet valve seated (holding float chamber cover upside down). This distance should measure $1\frac{19}{32}$" on 63AW-12 carburetors and $2\frac{1}{64}$" for 63AW-14 and 63AW-16 units.

Under three pounds fuel pump pressure the fuel level should measure $\frac{55}{64}$" on 63AW-12 units and $1\frac{3}{64}$" on 63AW-14 and 63AW-16 carbuertors.

Idle Mixture

For a preliminary adjustment, turn the needle into its seat and open one full turn. Run the engine until it reaches normal operating temperature and alter the adjustment as required to obtain smooth performance. The range should be between 1 and 1½" turns open.

Accelerator Pump

This adjustment is provided in the form of three grooves on the pump piston rod. The carburetor must be opened up and the vacuum pump piston assembly removed. Compress the spring toward the vacuum piston to permit moving the pump rod to the outer end of the slot in the pump piston base. At this point the slot is wide enough to permit removal of the rod.

There are three grooves near the end of the pump rod providing for three lengths of pump stroke. Install the pump piston in the groove nearest the end of the rod to obtain minimum or a half stroke; in the center groove for intermediate stroke, and in the third groove for maximum stroke. The spring holds the rod in the center of the pump piston base.

CARBURETOR GOVERNOR

Zenith

To change the governed speed, remove the seal wire and large seal plug, Fig. 14. Turn the main adjusting screw clockwise to increase or counter-clock-

Fig. 14 Zenith carburetor governor adjustments

wise to decrease governed speed. If the governor does not show definite response to changes of ¼ to one full turn of the adjusting screw, it indicates a defective governor.

If the governor "surges" or "hunts" to a higher or lower engine speed, remove the small seal plug and turn the compensating spring adjusting screw ¼ turn counter-clockwise until the surge is overcome.

If the governor does not respond quickly enough when governed speed is approached and the action "lags" or is "flat", turn the compensating adjusting screw clockwise until the symptom is overcome. Do not turn the adjustment more than ½ turn at a time without checking the performance of the vehicle on the road.

Holley Model 1174

Used with Holley carburetors, this governor, Fig. 15, is a vacuum controlled device featuring all the advantages of a mechanical governor without lengthy and complicated linkage. Should it become necessary to make any changes, proceed as follows:

Fig. 16 Vacuum screw adjustment. Holley 1174 governor

To adjust the governor cut-off speed, remove the seal from the screw on the side of the governor housing and remove the screw. Rotate the engine until the end of the governor rotor, which carries the adjusting screw, is in line with the hole from which the screw was removed. Turn the adjusting screw clockwise to increase or counter-clockwise to decrease governed speed.

Whenever the governor has been disassembled and serviced, after reassembling turn the adjusting screw clockwise until it stops, then turn it counter-clockwise three full turns. Final adjustment is then made after the governor has been assembled to the engine.

The vacuum adjusting screw, Fig. 16, regulates the rpm spread between the governor full load cut-off speed and the no-load engine speed. Turning the screw clockwise will decrease the rpm spread. Turning it counter-clockwise will increase the spread. Changing the position of the screw will change the average governor speed and this should be corrected by the rotor adjusting screw.

Clutch Section

BORG & BECK

These clutches, Fig. 1, are single plate, dry disc types with no internal provision for adjustment for wear. However, each release lever is adjusted individually to the correct height, and no attempt should be made to adjust these levers unless the clutch is to be dismantled for overhaul. Overhauling the clutch should not be attempted unless a clutch rebuilder is available. Lacking this equipment it is recommended that the clutch cover and pressure plate assembly be exchanged for a rebuilt unit.

Clutch Pedal, Adjust

The general procedure for adjusting the clutch pedal is to shift the pedal down away from the toe board until the clearance or free movement is 1 to 1½". The pedal pad should come in contact with the toe board when the pedal is pressed down. If it does not move that far, making it necessary to spring the pedal to make the pad touch the toe board, shift the pedal down a little more.

Press the pedal down and note the distance the release bearing travels after it comes in contact with the release levers. To obtain a clean release the levers should be pushed toward the flywheel $\frac{7}{16}$". If it does not travel this distance shift the pedal up, bearing in mind that the pedal pad must touch the toe board as above.

Clutch Assembly, Replace

After removing the transmission, but before removing the clutch, mark with a punch the flywheel, clutch cover and pressure plate so that these parts may be assembled in their same relative positions and in the same position on the flywheel if the same clutch is to be reinstalled. This is important because they are balanced as an assembly.

Fig. 1 Typical Borg and Beck clutch

To remove the clutch, pull out the clutch release bearing and sleeve. Unfasten the clutch cover from the flywheel, loosening each cap screw a few turns in succession until the cover is free. The clutch assembly and driven disc can then be removed from the flywheel.

When installing the clutch, coat the pilot bearing in the end of the crankshaft with wheel bearing grease. Clean the surfaces of the flywheel and pressure plate, making certain no oil or grease remains on these parts. Hold the cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the pilot bearing in the crankshaft. Bolt the clutch cover loosely to the flywheel, being sure the punch marks previously made are lined up. To avoid distortion of the clutch cover, tighten the cover bolts a few turns each in progression until all are tight. Guide the transmission into place, using care to see that the driven disc is not bent. Use a floor jack to support the transmission so that the clutch shaft may be guided through the driven disc safely. Adjust the clutch pedal free travel.

ROCKFORD TYPE TT

This type clutch, Fig. 2, is of the single plate dry disc type, consisting of a pressure plate and cover assembly having 12 or 15 release springs, three release levers and a spring-cushioned driven disc mounted on a splined hub. There is no internal provision for adjusting the clutch but each release lever is adjusted individually to the correct height. No attempt should be made to adjust these levers unless the clutch is to be dismantled for overhaul. Overhauling the clutch should not be attempted unless a clutch rebuilder is available. Lacking this equipment it is recommended that

the clutch cover and pressure plate assembly be exchanged for a rebuilt unit.

Clutch Assembly, Replace

Before removing the clutch from the flywheel, punch mark the flywheel, clutch cover and pressure plate so that these parts may be assembled in their same relative positions and in the same position on the flywheel if the same clutch is to be reinstalled. This is important because they are balanced as an assembly.

After removing the transmission, pull out the clutch release bearing and sleeve. Unfasten the clutch cover from the flywheel, loosening each cap screw a few turns in succession until the cover is free. The clutch and driven disc can then be removed from the flywheel.

When installing the clutch, coat the pilot bearing in the end of the crankshaft with wheel bearing grease. Clean the surfaces of the flywheel and pressure plate, making certain no oil or grease remains on these parts. Hold the cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the pilot bearing in the crankshaft. Bolt the clutch cover loosely to the flywheel, being sure the punch marks previously made are lined up. To avoid distortion of the clutch cover, tighten the cover bolts a few turns in progression until all are tight. Guide the transmission into place, using care to see that the driven disc is not bent. Use a floor jack to support the transmission so that the clutch shaft may be guided through the driven disc safely.

GENERAL DATA

Transmission Oil Pump

All Mack-made transmissions employ constant mesh helical gears which run free on the mainshafts and are brought into selective engagement by means of sliding gear-type clutches. These free-running or floating gears run on thin-shell bushings to maintain gear alignment with greater precision. However, because bushings require more positive provision for lubrication, pressure lubrication of these floating gears is provided by a built-in pump in all Mack-made transmissions except the small capacity TR-77 Series which is lubricated by gear throw-off and gear pumping action.

Pressure lubrication of these bushings is provided by oil delivered through rifle-drilled passages in the mainshafts and supplied by a simple eccentric shuttle-type pump built in the main drive pinion, Fig. 1. This pump has but one moving part—a double-ended reciprocating vane which dispenses with valves. Calculated leakage past the bronze nipple acting as a jumper tube, which conducts oil from the pump to the drilled mainshafts, supplies copious lubrication to the spigot bearings. Gravity feed oil reaches the reverse cluster gear bearings through a rifle-drilled connecting hole in the supporting shaft.

All working and sliding parts of Mack-made transmissions are bathed in oil from gear throw-off when the engine is running; the countershaft being partially submerged in lubricant. To supply the pump, part of this gear throw-off is collected by a gutter high on the right-hand side of the case. Through a drilled connecting passage in the case, this oil is led to the eccentric space between the driving pinion shaft and its bearing cover. As the shaft turns, the pump vane reciprocates in its eccentric orbit and the vane ends pick up the oil and force it into the center passage through the bronze nipple to the mainshaft drillings.

Magnetic Cleaner Plug

Of course, clean oil in a transmission is essential to long life of gears and bearings. Minute particles of steel, dislodged as a result of wear, form an abrasive of great destructiveness and tend to circulate with the oil. This greatly increases the wear on gear teeth and bearings unless means are provided to separate them from the oil. To combat this, all Mack-made transmissions are provided with a magnetic oil cleaner plug. As viewed from the rear of the transmission, Fig. 2, the oil cleaner is located high inside the transmission case on the right-hand side above the level of the oil. It is so situated that it receives the throw-off from the upper gears. The cleaner consists of an integral open trough and slanting baffle with a removable sheet metal cover, Fig. 3. At the bottom of the slanting baffle, a tapped hole in the case accommodates a large hex plug with a powerful built-in magnet installed from outside, Fig. 2.

It is not necessary to drain the case in order to remove the plug for cleaning or for removing sludge from the bottom of the trough. The oil cleaner plug may be removed at any time without losing any oil or disturbing other parts of the transmission. When removed, it carries all foreign matter with it which is easily removed from the magnet simply by

Fig. 1 Sectional view of typical Mack transmission oil pump and mainshaft drillings

wiping it clean. Remove sludge from the sump and then replace the plug in the case.

In the TR-51 and 13 Series of large Mack transmissions, magnetic drain plugs are also employed in addition to the magnetic cleaner plug to aid in extracting any magnetizeable particles from the lubricating oil.

Fig. 2 Section through rear of transmission showing magnetic cleaner plug

MACK 20 SPEED TRQ-72, 720

Disassembly, Figs. 4 and 5

Unless a complete overhaul is necessary, remove only those parts required to gain access to the faulty parts. Do not disturb parts having press fits unless replacement is necessary. In that case, use proper press setups and pullers so that usable parts are not damaged. After cleaning all transmission parts with suitable solvent, inspect each part thoroughly. Replace worn or damaged parts, staked nuts, gaskets and cotter pins to avoid subsequent transmission failures.

1. After removing transmission from vehicle and cleaning externally, mount unit in a suitable overhaul stand. Remove hand brake parts, clutch release bearing assembly with return spring, clutch release shaft and yoke, P.T.O. covers and gear shifter hand control levers.
2. Remove both case covers and lay aside for bench disassembly. Engage sliding gear and ALL sliding clutches so that the entire gearset is locked up. Remove cotter pin from drive flange nut and then remove nut. Install standard puller and remove drive flange. Remove both rear bearing covers and save countershaft rear bearing shim pack intact. Slide speedometer gear off of mainshaft.
3. Remove all case-to-case dowel bolts and capscrews. With a large enough nylon headed mallet, tap compound case and separate it and the enclosed parts from the main case. Lay enclosed parts aside.
4. Remove mainshaft rear bearing retainer capscrews, oil tube, countershaft rear bearing cone clamp plate and capscrews. Remove countershaft front bearing cover capscrews and use jackscrews to remove the cover. Remove main driving pinion cover capscrews and cover. Carefully remove oil pump vane from pinion and save. To remove pinion, tap on gear end of pinion with a nylon mallet and work assembly out of case. Lay pinion aside.
5. Remove mainshaft spigot bearing inner race retaining snap ring. With 4th and 5th speed sliding clutch against bearing inner race, tap on clutch with nylon mallet and remove both parts from mainshaft. Pry key out of mainshaft spline. With a small tool, rotate 4th speed gear thrust washer one spline tooth and slide washer off of mainshaft.
6. Butt a soft drift against forward end of mainshaft and with a hammer, drive mainshaft rearward to separate rear bearing from case.
7. Carefully slide gears, sleeve, thrust washer, fixed and sliding clutches from mainshaft while withdrawing mainshaft from rear of main case. Remove sleeve Woodruff key from mainshaft. Place mainshaft in a vise with soft jaws and pry retaining ring off of mainshaft rear bearing 2-piece thrust washer. Pry 2-piece thrust washer out of groove in mainshaft. Turn mainshaft over and remove oil tube, retaining snap ring and compound mainshaft spigot bearing. Remove from vise and press mainshaft out of rear bearing retainer and front cone. Remove bearing cone spacer shims and save. Remove remaining bearing cone with a segmented-type puller.
8. Remove reverse gear shaft lock and with puller 17-T-1425, withdraw gear shaft from case. Remove cluster gear, bearings and bearing spacer from case.
9. Slide countershaft rearward and partially through rear bearing opening. Install segmented puller on rear bearing cones and remove. With a soft steel drift, remove rear bearing cup from main case. When using a drift, be very careful not to damage part or case and apply alternate equal blows to opposite sides to prevent cocking of part in the case.
10. Tilt forward end of countershaft upward and remove entire assembly from case. Remove countershaft front bearing inner race and gear snap ring. For shops having a small capacity hydraulic press, press off one countershaft gear at a time. For shops having a large capacity hydraulic press, place countershaft assembly in press, slide length of heavy tubing over countershaft integral gears to engage 3rd speed gear and remove all gears in one operation.
11. Clamp gear end of main driving pinion securely in large bench vise with soft jaws. Unstake pinion bearing

Fig. 3 Showing oil pump and oil cleaner

Fig. 4 Mack 20 speed TRQ-720 transmission

nut and with a wrench, remove left-hand threaded nut. Remove ball bearing by pressing or tapping off. Turn pinion over and remove retaining snap ring and spigot bearing. Remove oil tube carefully and save.

12. Position compound case on arbor press table and press mainshaft out of case-mounted rear bearing retainer and cone. Carefully remove and save cone spacer and shims. Turn case over and remove compound mainshaft rear bearing retainer and compound countershaft rear bearing cup.
13. Press compound mainshaft out of LO-split gear, fixed clutch, LO-LO split gear, gear sleeve and rear bearing front cone. Turn shaft over and clamp in vise with soft jaws. Remove spigot bearing inner race from spigot, unstake nut and remove. Nut has left-hand threads. Slide fixed clutch, sliding clutch and HI-split gear off of shaft. Remove shaft from vise.
14. Remove bearing cup from compound countershaft constant-mesh gear. With segmented puller, remove rear bearing cone. Remove gears in hydraulic press one at a time or all in one operation, depending on capacity of press. Remove gear key from shaft.
15. Clamp flange of main case cover in bench vise and remove shifter and fork setscrews. Remove Welch plugs at shifter ends with shifter rails. Withdraw shifter rails from main case cover and at the same time remove shifters and shifter forks. *CAUTION: The spring-loaded balls over the shifter rails will fly out with CONSIDERABLE FORCE when released by withdrawing the rails. Therefore, it is advisable to hold a clean shop wiper over the holes while withdrawing the rails.* Be sure to save the balls, spring, and rail interlock pins for use at reassembly. Remove breather and toggle levers from top of cover.
16. Disassemble compound case cover in same manner. *Watch out for spring-loaded balls over rails when withdrawing rails from case!*

Inspection and Repair

1. Wash and clean all parts thoroughly in clean solvent and dry with moisture-free compressed air. Do not spin bearings with compressed air as damage to the bearing may result.
2. Replace bearings which are pitted and/or spalled. Replace lubricated bearings having excessive axial or radial clearances. Replace cases if outer races of bearings turn freely in case bores.
3. Replace gears having pitted or badly worn teeth. Replace gears with damaged internal or external teeth as a result of gear clashing. Floating gears having excessive radial clearance should be rebushed and bored to size.
4. Check all splines. If excessive wear is obvious, replace part or parts. Check thrust washers for scored surfaces or reduced thickness from excessive wear. Replace if either or both conditions prevail.
5. Check all gray iron parts for cracks and breaks. Case castings may be welded or brazed provided cracks do not extend into bearing bores or bolting surfaces. Replace or repair parts found to be damaged.
6. Check all other parts for wear and damage. Replace all parts that cannot be repaired or straightened. Replace all gaskets, damaged oil seals, O-rings, staked nuts and any part that shows mutilation. Replace poppet springs that have lost their tension. Clean up any threads that show mutilation.

Reassembly

NOTE: All working parts, especially the bearings, should be generously coated with SAE-30 oil while the transmission is being assembled. This will assure immediate lubrication when first starting and will prevent seizing of these parts. As moving parts are assembled, check frequently to see that they move freely.

1. Insert gear key in countershaft and press gears on one at a time. These gears have an interference fit and can be pressed on cold but for best results, the gears should be shrunk-fitted on shaft. With a heat lamp or hot oil, heat gears 270° to 300° F. for a period of not more than ½ hour. Oil shaft for each gear. Install gear snap ring, install front

(Z) GRIND THRUST WASHER TO OBTAIN TIGHT FIT IN GROOVE.

Fig. 5 Mack 20 speed TRQ-72 transmission. Model TRQ-720 is the overdrive version

bearing inner race on spigot and retain with its snap ring.

2. Install countershaft front bearing in case. Install bearing cover and gasket. Place countershaft assembly in case with small end extending out of rear bearing opening. Install rear bearing cup in case. Install tapered roller bearing cones back-to-back on rear end of countershaft and secure with clamp plate. Position countershaft in front bearing.

3. Insert gear key in compound countershaft and press gears on one at a time. These gears have an interference fit and can be p essed on cold but for best results, the gears should be shrunk-fitted on shaft. With a heat lamp or hot oil, heat gears 270° to 300° F. for a period of not more than ½ hour. Oil shaft for each gear. Press bearing cup in front end of compound countershaft constant-mesh gear and bearing cone on rear end. Push countershaft rear bearing cup in compound case and install shim pack and bearing cover. Temporarily assemble compound countershaft, case-to-case gasket and compound case to the main case and countershaft.

4. Preload countershaft bearings as follows: Lubricate all bearings with SAE-30 oil. Wrap a string around countershaft 2nd-speed gear (largest integral gear)several times. Attach a spring scale to looped free end of string and with a steady pull, rotate the assembly *SLOWLY*. Repeat this operation and adjust thickness of rear bearing shim pack until the rolling-drag of 8 to 11 lbs.-pull is read on the scale. When correct shim pack thickness is established, remove compound case and compound countershaft from main case.

5. Position reverse cluster gear shaft so that slot in end of shaft will permit shaft lock to engage it. Start shaft into case. Assemble roller bearings and spacer in cluster gear. Position assembled gear in case and with a nylon hammer, tap shaft into case and gear. Install shaft lock and lock capscrew after tightening 60 to 65 ft.-lbs. with soft iron wire.

6. On bench, install compound mainshaft spigot roller bearing in end of mainshaft (compound driving pinion) and retain with snap ring.
Place gear end of mainshaft in vise with soft metal jaws. Install rear bearing cone, bearing retainer with two cups, bearing cone shims, front bearing cone and bearing split thrust washer. Adjust bearing shim pack thickness until end-play is .001 to .005″ then press or drive positioning ring over split washer. Install 3rd-speed thrust washer Woodruff key in shaft.

7. Remove mainshaft from vise and start in main case through rear bearing hole. As mainshaft is advanced into working position, slide parts on mainshaft as follows: 1st-speed gear, reverse gear fixed clutch, reverse gear, 2nd-speed gear, 3rd-speed fixed and sliding clutches, 3rd speed gear, engage 3rd-speed gear thrust washer and 4th-speed gear sleeve with Woodruff key. Install 4th-speed gear on sleeve. Install 4th/5th-speed toothed thrust washer and with a small tool, move washer one tooth so that inner teeth align with mainshaft splines. Install washer key in deepened spline root and install 4th/5th-speed sliding clutch on splines and over inlaid key.

8. At this point the mainshaft rear bearing retainer should be seated in the main case. Install retainer capscrews and tighten 60 to 65 ft.-lbs., then lock heads together with soft iron wire. Install inner race of spigot bearing on front end of mainshaft and retain with snap ring.

9. Assemble mainshaft spigot bearing in gear end of main driving pinion and retain with snap ring. Turn pinion over and place in vise with soft metal jaws. Install pinion ball bearing and bearing nut. Tighten nut (left-hand thread) 400 to 500 ft.-lbs., then positive stake lip of nut to pinion in slot provided. Install oil tube in pinion gear end and install pinion assembly in transmission case. *Be very careful not to damage oil tube as it engages mainshaft.* Install oil pump vane in pinion and install bearing cover. Tighten cover capscrews 75 to 80 ft.-lbs.

10. At this point, the main case should be positioned in a vertical position with the pinion pointing downward. If overhaul stand is not used, block up bell housing so that end of pinion clears the floor.

11. Clamp compound mainshaft in vise with soft metal jaws or improvised holding device and assemble as follows: Slide HI-split floating gear and fixed clutch on front end of shaft, install clutch nut (left-hand threads) and tighten 400 to 500 ft.-lbs., then positive stake lip of nut to shaft in slot(s) provided. Install inner race of bearing on shaft spigot.

12. Slide LO-split floating gear on fixed clutch and install both parts on rear end of compound mainshaft. Install sliding clutch on fixed clutch. Install LO-LO-split gear sleeve on shaft then slide LO-LO floating gear on sleeve. Press bearing cone on shaft next to sleeve, install double-row cup, cone spacer and shims, then press rear cone on shaft. With a piece of tubing over flange splines, place assembly in a press and with a load on bearing cones, measure bearing end-play. Add or remove shims between cones until end-play is .003 to .007″ as read on a dial gage, then remove double cup and rear bearing cone.

13. Slide HI-split clutch on its fixed clutch. Install interconnecting oil tube in end of mainshaft and carefully engage spigot of assembled compound mainshaft with oil tube and spigot bearing in end of mainshaft. *Be very careful not to damage oil tube as it engages compound mainshaft spigot.* Place compound countershaft (assembled earlier) on countershaft rear bearing cone and make sure all gears are properly meshed.

14. Paint end of main case with a good gasket sealer compound and install case-to-case gasket. Carefully lower compound case down over assembled parts and see that bearings are properly seated. Install case-to-case capscrews and dowel bolts. Tighten 90 to 100 ft-lbs. Install double-row rear bearing cup in compound case. Install rear bearing cone and speedometer gear. Apply gasket sealer in case and gasket and install rear bearing retainer gasket. Install retainer and capscrews with lockwashers. Tighten capscrews 90 to 100 ft.-lbs. Dip drive flange oil seal in oil and install in rear bearing retainer. Install drive flange and nut. Return transmission to normal position.

15. Lock up gear train by engaging both sliding clutches of the compound gearset. Tighten drive flange nut 800 to 1200 ft.-lbs., then install nut cotter pin. Return all sliding clutches to their neutral positions.

16. Position main case cover in bench vise with soft metal jaws. Install transmission case breather and toggle shifter levers. Starting with 1st and reverse speed shifter rail, start rail in cover and shifter, with a small blunt tool compress detent ball and spring, push rail past compressed ball, through a shifter and into neutral position. Install large interlock pin next to rail just installed. Install 2nd and 3rd-speed rail in same manner. Install small interlock pin in 2nd and 3rd-speed rail then another large pin between. Install short 1st and reverse speed rail with fork then 4th and 5th-speed rail with fork and shifter. Install shifter and fork setscrews, tighten 45 to 50 ft.-lbs., then lock to shafts individually with soft iron wire. Install new Welch plugs in shifter rail openings. Remove from vise.

17. Place compound case cover in vise with soft metal jaws. Dip new rail oil seals in oil and install. Install LO-split rail in cover and fork. Install interlock pin between rails. Install HI-split rail in cover and fork. Install pipe plug in pin hole. Install fork setscrews and tighten 45 to 50 ft.-lbs. Remove cover from vise.

18. Apply gasket sealer compound to case openings and cover gaskets and install gaskets on cases. Position sliding gear and all sliding clutches in neutral position. Install both assembled covers and make sure the shifter forks engage the grooves in their mating parts. Install cover capscrews with lockwashers and tighten 55 to 60 ft.-lbs.

19. Apply sealer compound to all other cover gaskets and install covers and capscrews with lockwashers. Check for proper shifting and free rotation of gears. Install clutch release shaft, yoke bearing, return spring and any other external part that was removed for disassembly. Recheck all fasteners for correct torques and locking means. Install all plugs, then remove transmission from stand.

Fig. 6 Mack 20 speed TRQ-77 transmission

MACK 20 SPEED TRQ-77

Disassembly, Figs. 6 and 7

NOTE: Unless a complete overhaul is necessary, remove only those parts required to gain access to the faulty parts. Do not disturb parts having heavy press fits unless replacement is necessary. In that case, use proper press setups and pullers so that usable parts are not damaged. After cleaning all transmission parts with suitable solvent, inspect each part thoroughly. Replace worn or damaged parts, staked nuts, gaskets and cotter pins to avoid subsequent transmission failures.

1. After removing transmission from vehicle and cleaning externally, mount unit in a suitable overhaul stand. Remove hand brake parts, clutch release bearing assembly with return spring, clutch release shaft and yoke, P.T.O. covers and gear shifter hand control levers.
2. Remove ALL case covers and lay aside for bench disassembly. Engage sliding gear and ALL sliding clutches so that the entire gearset is locked up. Remove cotter pin from drive flange nut and then remove nut. Install standard puller and remove drive flange. Remove both rear bearing covers and save countershaft rear bearing shim pack intact. Slide speedometer gear off of mainshaft. Remove compound shifter rail ball poppet springs and balls. Through cover opening in top of compound case, remove setscrew from compound shifter control arm, withdraw long shifter rail from arm and both cases, then remove arm from compound case.
3. Remove setscrews from shifters and shifter forks in main case. Withdraw shifter rails from main case and at the same time remove shifters and shifter forks. CAUTION: *The spring-loaded balls under the shifter rails will fly out with CONSIDERABLE FORCE when released by withdrawing the rails. Therefore, it is advisable to hold a clean shop wiper over the holes while withdrawing the rails.* Be sure to save the balls, springs and rail interlock pin and balls for use at reassembly.
4. Remove all case-to-case dowel bolts and capscrews. With a large enough nylon headed mallet, tap compound case and separate it and the enclosed parts from the main case. Disassemble on clean bench.
5. Remove mainshaft rear bearing retainer capscrews and countershaft rear bearing snap ring. Remove main driving pinion bearing cover and countershaft front bearing cover capscrews. Remove bearing covers, connecting oil tube and tube seal as a unit and disassemble on bench.
6. Remove main driving pinion assembly from main case. Tap on gear end with nylon mallet if necessary to work it out of case. Clamp gear end securely in large bench vise with soft jaws. Unstake bearing nut and with wrench, remove nut. The threads are left-handed. Remove ball bearing by pressing or tapping off. Turn pinion over and remove retaining snap ring and spigot bearing from gear end of pinion.
7. Remove 4th/5th speed sliding clutch from mainshaft. Pry key out of mainshaft spline. With a small tool, rotate 4th speed gear thrust washer one spline and slide washer off of mainshaft.
8. Butt a soft drift against forward end of mainshaft and with a hammer, drive mainshaft rearward to separate rear bearing from case.
9. Carefully slide gears, sleeve, thrust washer, fixed clutch and sliding clutch from mainshaft while withdrawing mainshaft from rear of main case. Remove sleeve Woodruff key from mainshaft.
10. Clamp gear end of mainshaft securely in large bench vise with soft jaws. Remove retaining snap ring and pinion spigot bearing inner race from spigot end of mainshaft. Unstake rear bearing nut and with wrench, remove nut which also has a left-hand thread. Remove rear ball bearing and bearing retainer from main shaft. Turn mainshaft over and remove retaining snap ring

POSITIVE STAKING METHOD
USE SQUARE-NOSED PUNCH TO SHEAR METAL LIP OF NUT INTO MILLED SLOT ON SHAFT.

ALL FORKS IN SLIDING CLUTCHES SIDE-CLEARANCE___.005 TO .020

USE PULLER 17-T-1643

COMPOUND MOUNTING FLANGE FASTENERS

Fig. 7 Mack 20 speed TRQ-77 transmission

and compound mainshaft spigot bearing.

11. Remove reverse gear shaft lock and with puller 17-T-1643, withdraw gear shaft from case. Remove cluster gear, bearings and bearing spacer from case.
12. Slide countershaft rearward and partially through rear bearing opening. Install segmented puller on inside bearing cone and remove both cones. Remove countershaft case-mounted bearing parts with a soft steel drift. When using a drift, be very careful not to damage part or case and apply alternate equal blows to opposite sides to prevent cocking of part in the case.
13. Tilt forward end of countershaft upward and remove entire assembly from case. Remove countershaft front bearing retaining snap ring, bearing inner race and gear snap ring. For shops having a small hydraulic press, press off one countershaft gear at a time. For shops having a large capacity hydraulic press, place countershaft assembly in press, slide length of heavy tubing over countershaft integral gears to engage 3rd speed gear and remove all gears in one operation. Remove gear key.
14. Remove bearing cup from compound countershaft constant-mesh gear. With segmented puller, remove rear bearing cone. Remove gears in hydraulic press one at a time or all in one operation, depending on capacity of press. Remove gear key from shaft.

Inspection and Repair

1. Wash and clean all parts thoroughly in clean solvent and dry with moisture-free compressed air. Do not spin bearings with compressed air as damage to the bearing may result.
2. Replace bearings which are pitted and/or spalled. Replace lubricated bearings having excessive axial or radial clearances. Replace cases if outer races of bearings turn freely in case bores.
3. Replace gears having pitted or badly worn teeth. Replace gears with damaged internal or external teeth as a result of gear clashing. Floating gears having excessive radial clearance should be rebushed and bored to size.
4. Check all splines. If excessive wear is obvious, replace part or parts. Check thrust washers for scored surfaces or reduced thickness from excessive wear. Replace if either or both conditions prevail.
5. Check all gray iron parts for cracks and breaks. Case castings may be welded or brazed provided cracks do not extend into bearing bores or bolting surfaces. Replace or repair parts found to be damaged.
6. Check all other parts for wear and damage. Replace all parts that cannot be repaired or straightened. Replace all gaskets, damaged oil seals, O-rings, staked nuts and any part that shows mutilation. Replace poppet springs that have lost their tension. Clean up any threads that show mutilation.

Reassembly

NOTE: All working parts, especially the bearings, should be generously coated with SAE-30 oil while the transmission is being assembled. This will assure immediate lubrication when first starting and will prevent seizing of these parts. As moving parts are assembled, check frequently to see that they move freely.

GASKETS: So that the same instructions do not have to be repeated for every operation, we will state here that ALL new cover gaskets at final assembly are to be coated on BOTH sides with a good gasket sealer. When the attaching capscrews are tightened to their recommended torque values, the sealer will assure leak-proof joints between the covers and the case. The metal shell of oil seals that contact whatever retains them, should also be coated lightly with a good gasket sealing compound before installation.

In most cases, it is easier to coat metal parts rather than the gasket. The dry gasket can be placed in position on the transmission case since the sealing compound is adhesive enough to hold the gasket until the cover is attached over it and fastened by capscrews.

As a further measure against oil leakage, additional sealing compound should be applied around the entire joint of each cover under which there is either a shim pack or a gasket.

1. Insert gear key in countershaft and press gears on one at a time. These gears have an interference fit and can be pressed on cold but for best results, the gears should be shrunk-fitted on shaft. With a heat lamp or hot oil, heat gears 270° to 300° F. for a period of not more than ½ hour. Oil shaft for each gear. Install gear snap ring, install front bearing inner race on spigot and retain with its snap ring.
2. Install countershaft front bearing in case. Place countershaft assembly in case with small end extending out of rear bearing opening. Install rear bearing cup in case. Install tapered roller bearings back-to-back on rear end of countershaft and retain with its snap ring. Position countershaft in front bearing.
3. Insert gear key in compound countershaft and press gears on one at a time. These gears have an interference fit and can be pressed on cold but for best results, the gears should be shrunk-fitted on shaft. With a heat lamp or hot oil, heat gears 270° to 300° F. for a period of not more than ½ hour. Oil shaft for each gear. Press bearing cup in front end of compound countershaft constant-mesh gear and bearing cone on rear end. Push countershaft rear bearing cup in compound case and install shim pack and bearing cover. Temporarily assemble compound countershaft, case-to-case gasket and compound case to the main case and countershaft.
4. Preload countershaft bearings as follows: Lubricate all bearings with SAE-30 oil. Wrap a string around countershaft 2nd-speed gear (largest integral gear) several times. Attach a spring scale to looped free end of string and with a steady pull, rotate the assembly *SLOWLY*. Repeat this operation and adjust thickness of rear bearing shim pack until the rolling-drag of 9 to 12 lbs.-pull is read on the scale. When correct shim pack thickness is established, remove compound case and compound cluster gear from main case. Then continue reassembly of main case.
5. Position reverse cluster gear shaft so that slot in end of shaft will permit shaft lock to engage it. Start shaft into case. Make sure that gear is not in reversed position. Assemble roller bearings and spacer in cluster gear. Position assembled gear in case and with a nylon hammer, tap shaft into case and gear. Install shaft lock and lock capscrew with soft iron wire after tightening 30 to 35 ft.-lbs.
6. On bench, install compound, mainshaft spigot ball bearing in end of mainshaft (compound driving pinion. Place gear end of mainshaft in vise with soft metal jaws. Place mainshaft rear bearing retainer on shaft, then install bearing. Install bearing nut (left-hand thread) and tighten 400 to 500 ft.-lbs. Positive stake lip of nut into slot or slots provided in the mainshaft for this purpose. Install bearing inner race on mainshaft spigot and retain with snap ring.
7. Remove mainshaft from vise and start in main case through rear bearing hole. As mainshaft is advanced into working position, slide parts on mainshaft as follows: 1st speed gear, 2nd speed gear, 3rd speed fixed and sliding clutches, 3rd speed gear, thrust washer Woodruff key, thrust washer, 4th/5th speed gear sleeve, gear and thrust washer. At this point, the mainshaft rear bearing should be seated in the main case. Install bearing retainer capscrews and tighten capscrews 30 to 35 ft.-lbs., then lock heads together with soft iron wire.
8. With a small tool, move 4th/5th speed gear thrust washer one tooth so that inner teeth align with mainshaft splines. Install washer key in deepened spline root and slide 4th/5th speed sliding clutch on splines and over inlaid key.
9. Assemble mainshaft spigot bearing in gear end of main driving pinion and retain with snap ring. Turn pinion over and place in vise with soft metal jaws. Install pinion ball bearing and bearing nut. Tighten nut (left-hand thread) 400 to 500 ft.-lbs. then positive stake lip of nut to pinion in slot provided. Install pinion assembly in transmission case. On bench, insert oil tube in main driving pinion bearing cover, slide rubber seal over tube and then assemble countershaft front bearing cover on free end of oil tube so that this assembly is ready to be installed on the main case as an assembly. Apply a good gasket sealer to the case and

position bearing cover gaskets on case so that capscrew holes are aligned. (The sealer will hold the gaskets in place.) Apply gasket sealer to contacting surfaces of bearing covers and install covers over bearings. Install capscrews with lockwashers and tighten pinion cover and countershaft bearing cover capscrews 30 to 35 ft.-lbs.

10. At this point, the main case should be positioned in a vertical position with the pinion pointing downward. If overhaul stand is not used, block up bell housing so that end of pinion clears the floor.
11. Position compound mainshaft in arbor press with spigot end down. Slide LO-LO split floating gear and thrust washer on shaft. Remove snap ring from outer race of ball bearing and press bearing on shaft. Remove assembly from press and clamp in bench vise with soft metal jaws so that spigot end is up. Install LO/LO-LO split sliding clutch on splined shoulder of shaft. Slide LO-split floating gear and HI-split floating gear with sleeve on front end of compound mainshaft. Slide splined HI-split floating gear thrust washer on splines of compound mainshaft until it engages sleeve. With a small tool move thrust washer one tooth so that inner teeth align with mainshaft splines. Install washer key in deepened spline root so that it engages thrust washer and slot in HI-split floating gear sleeve. Slide DIRECT/HI-split sliding clutch on splined front end of compound mainshaft and over inlaid key, thus locking key in position. This sliding clutch is marked DIRECT on one end and it is *very important* that this end be assembled so that it will engage the driving pinion (mainshaft).
12. Loosen vise and hold assembled parts together while transferring assembled unit from bench to upright transmission. Install spigot end in ball bearing in gear end of driving pinion (mainshaft). Place previously assembled compound countershaft upright on rear bearing cone of main box countershaft and make sure all compound gears are properly meshed.
13. Paint end of main case with a good gasket sealer compound and install case-to-case gasket. Paint rim of gasket with sealer and lower compound case down over assembled shafts. Tap case into position so that bearings are seated properly, then install case-to-case capscrews and dowel bolts and tighten 75 to 80 ft.-lbs. Reinstall snap ring in outer race of compound mainshaft rear ball bearing. Install speedometer drive gear on shaft. Apply sealer compound and install rear bearing cover gasket and cover. Install cover capscrews with washers and tighten 120 to 130 ft.-lbs. Apply sealer compound to metal part of drive flange oil seal and install seal in rear bearing cover. Oil lip of seal, install drive flange and nut. Return transmission to normal position.
14. Lock up gear train by engaging sliding gear and all sliding clutches. Tighten flange nut 400 to 500 ft.-lbs. Install nut cotter pin.
15. Oil and install shifter oil seals in main case. On bench, install shifters on shaft ends. Starting with 1st and reverse speed shifter shaft, install spring and poppet ball in case, start shaft in case and with a blunt tool, compress spring-loaded detent ball and at the same time push shaft over ball. Engage 1st speed fork in sliding gear and push shifter shaft through fork hub and all the way into working position. Install fork setscrew, tighten and lock with soft iron wire. Install shifter shaft interlock ball next to shaft just installed, install poppet spring and ball in case for 2nd/3rd speed shaft, compress spring-loaded detent ball and pass 2nd/3rd speed shaft over it. Install interlock pin in shaft, engage 2nd/3rd speed fork with sliding clutch then push shaft on through and secure fork. Install interlock ball next to pin, start 4th/5th speed shifter shaft in case, compress detent springloaded ball and push shaft over it. Engage fork with 4th/5th speed sliding clutch and push shaft on through to working position. Secure fork to shaft. Tighten all shifter and fork set screws 45 to 50 ft.-lbs. Then lock with soft iron wire.
16. Through opening in top of compound case, install DIRECT/HI-split shifter fork in groove provided in sliding clutch. Also install LO/LO-LO split shifter fork in groove provided in its sliding clutch. Hold LO-LO split shifter fork in working position and insert its shift rail in compound case from the rear. Push rod in case and through hole in fork. Also hold rail shifter in working position and push rail through hole provided in shifter. Install setscrews in shifter and shifter fork. Make sure tapered end of setscrews enter locating detents in rail, then shift into neutral position. Install rail interlock ball in space provided between rails. While holding previously installed DIRECT/HI-split shifter fork in working position, insert its shift rail in compound case from the rear and push through hole provided in fork. Install fork setscrew and shift rail to neutral position.
17. Insert long compound control shift rail in hole provided in main case and push rearward until end appears at compound case. Engage compound control shifter arm in compound shifter slots and hold in working position. Continue pushing on long shift rail until it passes through control arm and into rear support hole. Install control arm setscrew. Tighten all four shifter and fork setscrews 40 to 50 ft.-lbs., then lock each setscrew to its rail with soft iron wire. Install compound shift detent balls and springs in holes provided at rear of case over the rails. Apply sealer to spring cover and rail end cover. Install gaskets, covers and capscrews with washers. Tighten capscrews 30 to 35 ft.-lbs.
18. Install travel-limiting pins for the shifter rails in holes provided. Check for free rotation of gears. Apply sealer compound to cover gasket and install on case. Assemble shifter toggle(s) to cover and install case cover. Install clutch release shaft, yoke, bearing return spring and any other external part that was removed for disassembly. Recheck all fasteners for correct torques. Install all plugs, then remove transmission from stand.

MACK 5 & 10 SPEED UNITS

In overhauling these transmissions, refer to Figs. 8, 9 and 10 and to the text which follows. Do not disturb sub-assemblies more than necessary to inspect parts and make repairs.

Disassembly

1. Remove case cover.
2. Lock gears by engaging two sliding clutches and remove drive flange.
3. On five speed units, remove mainshaft rear bearing cover.
4. Remove shifter rails and forks from main transmission.
5. Remove clutch collar, yoke and shaft.
6. On ten speed units, remove case-to-case capscrews and separate compound from main case.
7. On mono-shift units, remove shift cylinder and piston before separating cases. The internal parts of the mono-shift compound cannot be removed with the case because the forward synchronizer is retained by the main transmission mainshaft. Tap shift rail and mainshaft as cases are separated. Then disassemble synchronizer as necessary to remove mainshaft and cluster gear.
8. Remove drive pinion bearing cover together with forward countershaft bearing cover.
9. On units with direct drive on fifth, pull drive pinion together with bearing forward from case.
10. Remove mainshaft rear bearing retainer and slide mainshaft rearward as far as possible. Slide 4th and 5th speed clutch from shaft. Pry key from mainshaft spline and remove star washer from floating gear. Slide remaining parts from mainshaft as shaft is withdrawn through rear bearing opening in case.
11. Remove reverse idler gear cluster.
12. Remove bearing covers and lower countershaft.
13. On units with direct drive on fourth, the main drive pinion may now be removed by detaching the bearing retainer ring and withdrawing the bearing and pinion assembly through inside of case.
14. On ten-speed units, to pull the bearing for countershaft removal, make split bearing cup and retainer ring to fit over forward bearing rollers.
15. Tilt forward end of countershaft upward and remove assembly from case.

Fig. 8 Mack five speed transmission

Fig. 9 Mack ten speed, two stick transmission

Fig. 10 Mack ten speed monoshift transmission

Sub-Assemblies

Compound Mainshaft—On two-stick jobs, support floating gear on heavy tubing. Then press shaft through bearing and case.

Countershaft Gears—Remove countershaft front bearing inner race and gear snap ring from shaft. Slide length of heavy tubing over countershaft to engage 3rd speed gear. Place assembly in 75-ton press and remove all gears in one operation. Mated gears, if defective, must be replaced in matched sets.

Floating Gear Bushings—Be sure to align oil holes. Press bushings in .010″ to .015″ below face of bore and force bushing into four notches before burnishing. Lubricate broach with a water soluble oil mixture. Recess opposite end of bushing .035″ to .040″ after burnishing and then break sharp corner of bushing.

Reassembly

1. Lubricate all moving parts during assembly to insure initial lubrication when first run. As moving parts are assembled, check frequently to see that they are free.
2. Position countershaft and gear assembly in case.
3. Install countershaft bearing components (also compound case and

No Clash All Around *Clash at One End Only* *Clash at Both Ends*

Fig. 11 Adjustment of shift rail rocker eccentric pivot pin

countershaft when 10-speed) with trial shim pack under rear bearing cover. Wrap cord around 2nd speed gear and check for 9¼ to 12¼ lb. rolling drag. Make corrections by changing shim selection. Remove compound case and countershaft to allow installation of mainshaft.

4. Install main drive pinion.
5. Install reverse idler gear cluster.
6. Start mainshaft from rear of case and slide mainshaft components into place as shaft enters case, checking end play and clearance of components as assembly progresses.
7. On 10-speed units, assemble compound mainshaft and countershaft. When mono-shift, be sure each synchronizer pack has .020″ to .040″ clearance.
8. Install shifter rails and forks, compound case (10-speed), case cover, bearing covers and drive flange.
9. Assemble clutch release collar on driving shaft pinion. Then install release shaft and yoke.

Shift Rail Rocker Pivot Pin, Adjust

The shifter mechanism includes a 1st and reverse shift rail rocker, carried by an adjustable eccentric pivot pin mounted in the transmission case cover. This arrangement not only shortens the shift into first speed and eliminates the awkward U-shift from 1st to 2nd speed as in some shift patterns, but at the same time, equalizes the travel length of each shift by bringing all forward shifts into orderly progression.

In overdrive transmissions, an additional rocker and pivot pin to operate the 4th and 5th speed sliding clutch, converts the shift pattern of these transmissions to that of the direct-drive units. Thus, either type of transmission has the same standard shift.

1. With engine running at idle speed and with hand shifter lever in neutral position, loosen the shift rail rocker pivot pin lock nut and adjust the pin as follows:
2. Left illustration, Fig. 11. Rotate pin to fore and aft position in one direction. If no gear clash is felt or heard, rotate pin to fore and aft position in the opposite direction. If no gear clash is felt or heard in either extreme eccentric position of the pin, reverse the rotation of the pin until flats are 90° to the transmission centerline and lock the pin in the halfway position.
3. Center illustration, Fig. 11. If gear clash is felt or heard in one direction and not in the fore and aft position in the opposite direction, move the pin back to the midpoint between point of gear clash and the fore and aft position. Lock pin at this midpoint.
4. Right illustration, Fig. 11. If gear clash is felt or heard in both directions, note position of flats, and position the pin midway between points of gear clash and lock in this position.

S.R.—Single reduction. D.R.—Double reduction. 2-Sp. D.R.—Two-speed double reduction.

SINGLE REDUCTION AXLES

Type With Straddle-Mounted Pinion, Fig. 1

These single-reduction axle carriers have either a spiral bevel or hypoid gearset. Machined bosses on the differential bearing pedestal caps register against corresponding machined diameters in the axle housing to restrict pedestal deflection and thus insure proper meshing of the gearset under load.

The pinion and side gears of the four-pinion type differential are backed up by bronze washers to take the thrust, and the pinion gears are bronze bushed to the spider. These parts are enclosed in a differential case consisting of two mated halves bolted together, carried in a pair of tapered roller bearings. The bearings are mounted in the pedestals and can be adjusted by nuts at the outer cups. These nuts also permit positioning

Fig. 1 Typical Mack single-reduction rear axle with straddle-mounted pinion

Fig. 2 Mack single-reduction carrier showing bearing preloads and screw torques

of the ring gear for proper tooth contact. Body-fitted capscrews secure the ring gear to the differential case.

The drive pinion is straddle-mounted, with a spigot bearing at the gear end. Two tapered roller bearings, back-to-back and carried in a separable housing, support the drive flange end and restrict end thrust. Bearing adjustment is obtained by varying the length of the spacer between the bearing cones, and tooth contact is adjusted by shims between the carrier and pinion bearings.

Deflection of the ring gear under load is restrained by an adjustable shoe, in back of the gear, opposite the point of contact with the drive pinion.

As a guide in servicing these axles, see the procedure outlined in the *Rear Axles* chapter for Timken Single-Reduction units.

Fig. 3 Mack CRS-76 single-reduction carrier showing bearing preloads and screw torques

Type Without Pinion Spigot Bearing, Figs. 2 & 3

These single-reduction axle carriers have a spiral bevel gearset. A separate housing, attached to the carrier housing by capscrews, is the mounting for the tapered roller bearings which carry the drive pinion. The ring gear and three-pinion differential are supported by another pair of tapered roller bearings mounted in the carrier housing differential bearing pedestals. Positively torqued capscrews are used in all bolting locations, thus eliminating the use of studs or bolts.

Machined bosses on the pedestal bearing caps register against corresponding machined diameters in the axle housing to restrict pedestal deflection and thus insure proper meshing of the gearset under load. Deflection of the ring gear under load is restrained by an adjustable shoe in back of the gear, opposite the point of contact with the drive pinion.

The drive pinion bearing arrangement has been designed so as to take the thrust load developed without endwise movement of the pinion. Bearing adjustment is obtained by varying the length of the spacer between the outer bearing cone and the shaft shoulder. Gear tooth contact is adjusted by varying the shim pack thickness between the carrier and drive pinion housings and adjusting the position of the ring gear.

The differential pinion and side gears are backed up by bronze washers to take the thrust, and the pinion gears are bronze bushed to the spider. The casing halves are machined with thick-walled steel forgings having wide, mated bolting flanges. A ring of capscrews clamp the casing halves together and thus form a rigid enclosure for the differential parts. This type of casing construction distributes driving torque and pressures equally. The left-hand differential casing has a splined pilot which engages internal splines of the ring gear. Another ring of capscrews attach the gear to the left-hand casing bolting flange. Driving torque is transmitted from the ring gear through the splines to the differential, thus relieving the gear capscrews of any shearing action. Slotted adjusting nuts, which bear against the differential bearing cups, are threaded to the pedestals to provide for the preloading of these bearings and also provide a means of positioning the ring gear for proper tooth contact.

One involute spline on the differential casing flanged half and the mating involute space on the ring gear are marked to facilitate aligning the ring gear bolt holes when assembling.

DOUBLE REDUCTION AXLES

A typical Mack double-reduction carrier is shown in Fig. 4. It has a spiral bevel gearset for the first reduction and helical gears for the second reduction.

Tapered roller bearings are provided throughout. And as is the case with the single-reduction carrier described above, the pinion bearings are preloaded by varying the length of the spacer between the bearings, and differential bearings are preloaded by adjusting nuts. The cross shaft bearings are preloaded by proper selection of shims. Proper pinion and ring gear tooth contact is obtained by varying shim packs "G" and "D", Fig. 4.

As a guide to servicing these carriers, see the *Rear Axles* chapter for double reduction repair procedures. Figs. 5 and 6 show the bearing preloads and screw torque requirements on two models of these carriers.

Fig. 4 Typical Mack double-reduction axle carrier

bearing housing which is fastened to the front of the carrier housing.

Beyond the differences stated above, both carriers are the same. The spur pinion shaft and spiral bevel gear mounted at right angles to the bevel pinion shaft, are carried by a pair of tapered roller bearings, one mounted in the carrier housing and the other in a separable bearing retainer. Proper bevel gear mesh is obtained by varying the thickness of the shim packs between the carrier housings and the pinion gear housings or retainers.

Body-fitted bolts clamp the bull gear to the differential casing which also carries the differential pinion gears. Long body-fitted through bolts clamp the casing between the casing covers, thus forming an enclosure for the differential side and pinion gears. This assembly turns in a pair of tapered roller bearings at the outer ends of the casing covers, the bearings being mounted in the carrier pedestals. Preloading of these bearings is provided for by a slotted adjusting nut threaded to the inboard side of the right-hand bearing cup.

TANDEM AXLES

These tandem double-reduction axle carriers, Fig. 7, 8 and 9, each have a spiral bevel gearset for the first reduction, spur gears for second reduction and a three-pinion type differential. In addition, the forward carrier has an inter-axle power divider which consists of a driving cage, plungers, male and female cams. The driving cage carries two rows of stagger-indexed plungers which reciprocate between the male and female cam lobes when unequal resistance is offered by the cams and are stationary when equal resistance is offered. The female cam drives the forward carrier and the male cam, connected through the inter-axle propeller shaft, drives the rearward carrier.

A separable housing, fastened to the front of the forward carrier by capscrews, contains the inter-axle power divider with the drive pinion and through shaft in a quill arrangement. The pinion is carried in a pair of tapered roller bearings and has a spigotted roller bearing at the forward end to maintain power divider cage and outer cam alignment.

In the rearward carrier, the drive pinion shaft is carried by a pair of tapered roller bearings in a separable

Steering Gear Section

GEMMER STEERING GEAR

Worm & Roller Type, Fig. 1

This steering gear has an hour-glass shaped worm meshing with a three-toothed roller which is offset in its relation to the worm centerline. Made with integral cones the worm is attached to the steering column tube and held between tapered roller bearings. The upper bearing cup is pressed into the steering gear housing, whereas the lower cup has a slip fit to permit bearing adjustment. A shim pack between the worm cover and the housing provides for end play adjustment.

The roller shaft turns in two bronze bushings on the steering gear lever side, and in a straight roller bearing at the stub end. End thrust is controlled by a split washer which engages a groove close to the stub end of the shaft and adjustment is by means of a shim pack between the washer and cover hub. A yoke, integral with the shaft, embraces the roller which turns on two needle bearings, held between thrust washers. The shaft has a serrated end to engage the steering gear lever which is secured by a lockwasher and nut.

There is a self-adjusting, prepacked ball bearing near the upper end of the steering column tube.

Adjustments

Adjustment of the steering gear must be made in the sequence given below after disconnecting the gear from the linkage by removing the ball stud from the steering gear lever.

Gear Alignment

Loosen the steering gear housing stud nuts at the frame just enough to allow the housing to shift and line up at the angle determined by the steering column support bracket, and retighten the stud nuts. Loosen the capscrews at the steering column support bracket and allow the screws to shift in the bracket holes to match the gear column position, and retighten. This will correct any possible misalignment and must be performed before proceeding with the adjustments.

Worm End Play

Turn the steering wheel two turns to the right from the straight-ahead position and fasten it securely. Grip the jacket tube firmly just below the steering wheel hub, with the side of the finger barely touching the lower end of the hub. Then have a helper shake the steering gear hard; end play in the worm bearings will be felt at the wheel hub. Do not confuse side play in the jacket tube bearing with end play.

To remove end play, loosen the worm housing cover screws. Use a knife to remove one shim, taking care not to mutilate the remaining shims. Tighten the cover and check end play. Turn the

Fig. 1 Gemmer worm and roller steering gear

Fig. 2 Ross cam and lever steering gear with roller mounted twin studs

steering wheel to determine if any stiffness exists. Repeat until end play is removed and no stiffness exists.

Mesh Adjustment

Turn the steering wheel to the mid-position of its travel and shake the steering gear lever to check backlash. If backlash exceeds $\frac{1}{32}$", measured at the lever ball, the roller shaft must be adjusted.

Before changing the adjustment, attach a spring scale to a spoke at the rim of the steering wheel and measure the pull necessary to rotate the wheel. To adjust the mesh, be sure the steering wheel is located in the mid-position of its travel. Remove the roller shaft adjustment locknut plate and nut and slip off the semi-circular thrust washers. There are two thicknesses of shims to permit close adjustment. Remove shims of the proper thickness to take out all play in this position without increasing the pull at the steering wheel more than one pound over the pull required previously. It is better to have a slight amount of play between the roller and worm than to remove too many shims and set up a tight adjustment. The adjusting lock nut must be tightened securely to prevent rotation of the shims and thrust washer. Select a position of the lock plate that will lock the adjusting nut when tightened securely, using lockwasher and nut.

Fig. 3 Ross cam and lever steering gear with twin studs

ROSS GEAR

Twin Lever Mounted Type

These steering gears, Figs. 2 and 3, are the cam and twin lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel-backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove, causing the lever arm to rotate the lever shaft. The pitman arm, which is clamped on the splined end of the lever shaft and moves with it, turns the front wheels through the linkage.

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link from the pitman arm and loosening the steering column braces.
2. Loosen the lock nut and adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the four upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are of .002", .003" and .010" thickness.
4. Clip and remove one thin adjusting shim and then tighten down the cover with the four nuts and check the adjustment. There shoud be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim.
5. If necessary, remove or replace shims until the adjustment is correct.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right and from this point count the number of turns required to reach the end of travel to the left. Turn the wheel back exactly half this number of turns which is the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. *The gear must not bind in any position. A slight drag should be felt in the mid-position only.*
3. After proper adjustment has been made, tighten the adjusting screw lock nut and recheck the gear for binding.

Stud Roller Bearing, Adjust

In most cases the adjustments outlined above will be adequate. However, in some cases it may be necessary to adjust the stud roller bearing units in the lever shaft.

The roller bearings should be preloaded at all times. A heavy drag should be felt when revolving the studs by hand. If a torque wrench is available, the bearings should be adjusted as follows:

Lever Shaft Dia.	Torque to Revolve Stud
1⅜"	3-4 in. lb.
1½"	3-4 in. lb.
1⅝"	4-8 in. lb.
1¾"	5-11 in. lb.

1. With lever shaft removed from steering gear housing, wash the bearings in solvent and blow dry with compressed air, using care not to spin the bearings. Lubricate bearings with light oil.
2. Straighten out prong of locking washer to release stud nut. Remove nut and install new locking washer.
3. While holding stud from turning with a suitable spanner wrench on the locking washer, tighten the nut as required to bring it within the proper torque limits.
4. When proper adjustment has been secured, bend prong of washer against side of nut to keep it from turning.
5. Lubricate bearings with gear oil and assemble lever shaft in gear housing.

Column Alignment

After the steering gear has been reassembled and all adjustments completed, tighten the mounting bracket as well as the column upper bracket and braces. If necessary, renew the bushing in the column top bracket. The steering column must not be sprung in any direction, and any misalignment must be corrected or it will produce stiffness in the steering gear.

DESCRIPTION

This engine, Fig. 1, is a direct injection unit. Except for the fuel system, the engine is similar in construction to any conventional six cylinder overhead valve engine.

The fuel injection pump is of the distributor type, mounted vertically on the left side of the engine and driven through a worm gear from the auxiliary shaft.

The fuel pump incorporates an automatic advance and retard mechanism and the engine speed is controlled by a hydraulic governor incorporated in the fuel pump.

A fuel lift pump of the diaphragm type and equipped for hand priming is mounted on the cylinder block right side and is operated by an eccentric on the engine camshaft. The nozzles are located on the left side of the cylinder head.

TROUBLE SHOOTING

Engine Fails To Turn Over

1. Starting motor inoperative.
2. Faulty battery.
3. Faulty cables and terminals.
4. Starting switch defective.
5. Internal seizure.
6. Engine oil too heavy.

Engine Turns But Will Not Start

1. Fuel system faulty due to injection pump not operating properly or fuel lines clogged or air in lines.
2. Battery charge low; does not turn engine fast enough.
3. Air intake restricted or exhaust clogged.

Engine Does Not Develop Full Power

1. Moisture in fuel tank.
2. Fuel oil filter and strainer clogged.
3. Air cleaner clogged.
4. Insufficient fuel.
5. Poor fuel.
6. Injection pump not operating properly or not properly timed to engine.
7. Air leaks around intake manifold.
8. Exhaust restricted.
9. Lack of compression.
10. Air in fuel system.

Loss of Oil Pressure

1. Low lubricating oil level.
2. Clogged oil filter.
3. Oil leaks.
4. Engine oil pressure indicator or line defective.
5. Worn main, rod or camshaft bearings.
6. Dirt in oil filter relief valve or relief valve spring broken.
7. Oil pump worn.
8. Oil diluted or not as specified.
9. Defective cylinder head gasket.
10. Broken valve spring.

Lack of Compression

1. Valves sticking.
2. Worn pistons, rings and cylinder walls.

Smoky Exhaust

1. Engine overloaded.
2. Incorrect grade lubricating oil.
3. Worn valve guides, valve stems, pistons and sticky or worn oil control rings.
4. Air cleaner pipe clogged.
5. Improper fuel.
6. Defective injection nozzle.
7. Too much oil in air cleaner.
8. Incorrect valve adjustment.
9. Injection pump not properly timed.

Engine Overheats

1. Insufficient coolant in system.
2. Radiator cap loose.
3. Loose hose connections.
4. Fan belt slipping.
5. Cooling system clogged.
6. Dirt or trash on outside of radiator.
7. Lack of sufficient lubricating oil.
8. Engine overloaded.
9. Clogged oil filter.
10. Thermostat inoperative.
11. Water pump defective.
12. Engine oil diluted with fuel.

Excessive Lubricating Oil Consumption

1. Oil leaks.
2. Worn valve guides, piston rings, pistons and clogged oil control rings.
3. Incorrect grade of lubricating oil.
4. Overheated engine.
5. Excessive oil in crankcase.

Engine Knocks

1. One or more cylinders misfiring.
2. Loose connecting rod.
3. Poor grade of fuel or water in fuel.
4. Injection pump timed incorrectly.
5. Incorrect engine temperature.

Bearing Failure

1. Low oil pressure.
2. Lack of oil.
3. Engine runs too hot.
4. Loose bearings.
5. Improper lubricating oil.
6. Foreign materials entering engine.
7. Oil lines clogged.
8. Connecting rod bent.
9. Crankshaft out of alignment.

Valves Sticking

1. Valve springs weak or broken.
2. Gummy deposits from inferior fuel or oil.
3. Valve stems scored or carboned.
4. Insufficient clearance between valve stem and guide.

Piston & Cylinder Wear

1. Oil of unsuitable grade or viscosity.
2. Piston rings stuck or broken.
3. Foreign materials entering engine.
4. Piston rings not fitted properly to cylinder.
5. Dirty containers used for lubricating oil.

Engine Operates Unevenly or Vibrates

1. Valve and spring assembly inoperative.
2. Incorrect injection pump timing.

ENGINE, REPLACE

1. Remove air cleaner.
2. Disconnect fuel inlet line and fuel by-pass line from fuel injection pump.
3. Disconnect throttle control lever at pump.
4. Disconnect fuel shut-off control rod on pump.
5. Disconnect exhaust pipe at manifold.
6. Disconnect wiring harness from generator, starter, temperature sending unit and oil pressure sending unit.
7. Remove vacuum line from vacuum pump (if equipped).
8. Remove tachometer drive cable.
9. Disconnect engine ground strap.
10. Attach a suitable sling to the engine and position hoist for supporting engine.
11. Disconnect engine mountings and detach bell housing from flywheel housing.
12. Pull engine forward slightly to clear transmission and lift from chassis.
13. Reverse removal procedure to install.

CYLINDER HEAD

Removal

1. Remove fuel filter complete with pipes.
2. Remove breather pipe.
3. Take off cylinder head cover.
4. Remove rocker arm shaft assembly.
5. Remove push rods.
6. Remove nozzle leak off pipes.
7. Remove pressure pipes to nozzle.
8. Remove nozzles.
9. Unfasten and remove cylinder head complete with intake and exhaust manifolds.

Installation

1. Before installing the cylinder head, it is extremely important to be certain that the cylinder block and head machined surfaces are perfectly clean.
2. Care must be taken to make sure that the rocker arm shaft oil feed passage, Fig. 2, is not obstructed.
3. Use a new gasket when replacing head. Cover both sides with a thin coating of sealing compound. The gasket is marked "Top" and "Front" on the right-hand corner to indicate how it should be installed.
4. When head is installed, tighten stud nuts to the torque specified in the Engine Tightening Table and in the order shown in Fig. 3.
5. With push rods in position, replace rocker arm shaft assembly. Be sure that rubber sealing ring is correctly positioned on the oil pipe before tightening rocker arm assembly.
6. Install nozzles, leak-off pipes and attach pressure pipes to nozzles.

Fig. 1 Sectional view of Perkins D-354 engine

Fig. 2 Be sure oil feed hole indicated is unobstructed

Fig. 3 Cylinder head tightening sequence

VALVE LASH, ADJUST

When adjusting valve clearance, the engine should be turned to bring the respective piston to TDC on the compression stroke.

To adjust, loosen the lock nut and, with a feeler gauge between the top of the valve stem and rocker arm face, Fig. 4, turn the adjusting screw with a screwdriver until the correct clearance is obtained. Tighten lock nut. *Valve clearance should be set hot to the clearance given in the Valve Table.*

After warming up the engine, it should be shut down and the cylinder head nuts again tightened to the specified torque and in the order shown in Fig. 3. After tightening the nuts, recheck valve clearance and reset as required.

Replace cylinder head cover, using a new gasket and being sure it is positioned properly.

VALVES, REMOVE

Referring to Fig. 5, compress the spring caps and springs with a valve spring compressor and remove valve keys. Remove spring caps, springs and oil deflectors from intake valve stems. Turn the cylinder head upside down and remove the valves.

Fig. 4 Adjusting valve lash

Fig. 5 Valve components

Fig. 6 Recommended valve seat widths

All original valves are numbered consecutively from 1 to 12, commencing from the front of the engine. The cylinder head is marked with corresponding numbers opposite the valve seats.

VALVES, GRIND

Fig. 6 illustrates the recommended valve seats to be obtained. The intake seats may be narrower than the exhaust because they are larger in diameter, thus providing a total seat area approximately equal to smaller exhaust valve with the wider seat. Also the less severe heat conditions do not require as large a seat area for heat dissipation purposes.

There are also objections to an excessively wide seat. In city or light delivery service, a wide seat collects carbon and particles of dirt that will produce variations or loss of compression, resulting in poor idle and possibly a loss of general performance and economy.

A wide seat in severe service, operating in the presence of dirt or an excess of carbon, will produce a badly pitted seat which may be just as detrimental to valve life as a too narrow seat. Under these conditions, a seat width to the minimum limit would possibly be better. However, the source of trouble (dirt, carbon) should be eliminated, making it possible to retain the wider seat.

VALVE SPRINGS

Valve springs should be checked by measuring their free length, and the uniformity should not vary more than $\frac{1}{16}$".

Each spring should also be checked for squareness. This can be done with a steel square and surface plate. Stand each spring and the square on end on the surface plate and slide the spring up to the straight edge of the square. Then gradually revolve the spring, while at the same time noticing the space between the top coil of the spring and the square. This space should not exceed $\frac{1}{16}$"; if more, replace the spring.

Fig. 7 Testing valve springs

Fig. 8 Incorrect valve guide installation

Fig. 9 Rocker arm shaft assembly

Valve springs should be checked for tension with a spring tester, Fig. 7. Any spring that does not conform to the specifications listed in the chart within 10% should be replaced.

VALVE GUIDES

Clean valve guides with a suitable cleaning tool. Then check each valve guide with a "GO and NO-GO" gauge, if available; otherwise, use a new valve to check the fit. If the "NO-GO" portion of the gauge enters, the guide must be replaced.

Fig. 10 Checking push rods

Fig. 11 Removing fuel supply pump

Fig. 12 Removing camshaft gear

Fig. 13 Removing fuel injection pump drive gear

Clearance in excess of .006″ for intake valves and .008″ for exhaust valves, calls for replacement of valve guides, Fig. 8.

New guides should be installed so that the distance from the cylinder head to the top of the guide is ⅝″.

ROCKER ARMS

Wash rocker arm assembly thoroughly in solvent. Examine the rocker arms for wear. They should be an easy fit on the shaft without excessive side play. Should it be necessary to disassemble, reassemble as shown in Fig. 9.

PUSH RODS

Examine push rods for straightness by placing them on a flat surface and turning them as illustrated in Fig. 10. Bent push rods should be discarded and replaced with new ones.

VALVE LIFTERS

Valve lifters are of the mushroom type operating in guide holes bored in the cylinder block. To remove the lifters, therefore, it is necessary to take out the camshaft and remove the lifters through the bottom of the engine.

TIMING CASE & CAMSHAFT

Removal

1. Remove rocker arm assembly.
2. Remove inlet and outlet connections to fuel supply pump.
3. Remove fuel supply pump, Fig. 11.
4. Remove valve lifter inspection covers and withdraw push rod.
5. Remove crankshaft pulley.
6. Remove fuel injection pump gear cover and camshaft gear cover from timing case.
7. Remove camshaft gear, Fig. 12.
8. Remove fuel injection pump drive gear by unscrewing three bolts, Fig. 13.
9. Remove timing case.
10. Raise valve lifters and withdraw camshaft and thrust washers. If engine is removed from vehicle, it is advisable to turn it on its side or upside down to prevent valve lifters from falling out of their bores.
11. When camshaft has been withdrawn, remove valve lifters from bottom of engine if necessary.

Camshaft, Install

1. Raise valve lifters to be sure that they will clear the cams and carefully slide the camshaft into the engine.
2. Install the thrust washer into the machined recess in the front of the cylinder block and locate it on the dowel.

Timing Case, Install

1. The thrust washers on the camshaft and auxiliary drive shaft are sandwiched between the timing case rear face and the front face of the cylinder block. Care should be taken to see that they are not misplaced before installing the timing case.
2. Using a new gasket between timing case and cylinder block, place timing case in position and secure it to the cylinder block.

Camshaft Gear, Install

1. Turn engine over to bring Nos. 1 and 6 cylinders at top dead center.
2. Align keyway in camshaft gear with key in camshaft.
3. Align tooth on camshaft gear with the single dot between the teeth on the idler gear marked with a double dot.

Fig. 14 T.D.C. marks on crankshaft and pulley

Fig. 15 Removing idler gear

Fig. 16 Installing idler gear hub

4. Draw the gear onto the camshaft by using a heavy flat washer and a bolt.
5. Secure gear to camshaft by installing the retaining washer, tab washer and bolt.

Crankshaft Pulley, Install

1. Place camshaft gear cover on timing case.
2. Install pulley on crankshaft in such a position that the dot on the front face of the pulley aligns with the "V" groove on the end of the crankshaft, Fig. 14.

Fig. 17 Removing fuel injection pump

Fig. 18 Removing auxiliary drive shaft

Fig. 19 Auxiliary drive shaft thrust washer

IDLER GEARS & HUBS

The idler gear hubs are fitted in the front face of the cylinder block and can be removed by first unscrewing the self-locking nuts and withdrawing the idler gears, Fig. 15. The hubs can then be removed by lightly tapping and pulling them at the same time.

When replacing the idler gear hubs, it is important that the recessed ends be installed toward the cylinder block and located by the hollow dowels which also serve as the oil feed, Fig. 16.

After the hubs have been placed in position, turn the crankshaft until Nos. 1 and 6 pistons are at top dead center and place the idler gears on their respective hubs. *Be sure that the double dot timing mark on the idler gear to the camshaft coincides with the single dot timing mark on the crankshaft gear.*

FUEL INJECTION PUMP

Removal

1. Remove fuel injection pump lines connecting pump to nozzles.
2. Disconnect low pressure fuel pipes.
3. Cover fuel injection pump ports with suitable caps to keep out dirt.
4. Disconnect all fuel injection pump controls.
5. Unfasten and withdraw pump, Fig. 17.

Installation

1. Fit fuel injection pump gasket to pump mounting face.
2. Align master spline on pump shaft with master spline on vertical drive, and the scribed line on pump mounting flange with scribed line on adapter plate.
3. Secure pump to adapter plate and install fuel pipes.

FUEL PUMP DRIVE

Removal

1. Remove timing case.
2. Remove fuel injection pump.
3. Withdraw drive shaft and two half moon shaped thrust washers, Figs. 18 and 19.
4. Remove fuel injection pump adapter plate.
5. Remove oil pan and lube oil pump.
6. Tap out fuel injection pump vertical drive shaft from inside of crankcase.

Injection Pump Drive Gears, Install

When the injection pump drive has been removed, it should be examined and damaged or worn parts replaced. If the bronze gear requires replacing, it can be removed from the shaft by first removing the ball bearing, then pulling off the gear after releasing the four set screws, Fig. 20. The new gear can then be pushed on the shaft and secured by the set screws and the ball bearing replaced.

Injection Pump Drive, Install

1. Install vertical injection pump drive by inserting the ball race end of the assembly into the housing in the cylinder block and pressing into position.
2. Install injection pump adapter plate. *It is important when installing the plate that the scribed line on the edge of the plate is adjacent to the outside fuel pump attaching stud.*
3. Install lubricating oil pump and pan.

Fig. 20 Fuel injection pump drive shaft parts

Fig. 21 Checking backlash between gears

Fig. 22 Fuel injection pump timing pin location

AUXILIARY DRIVE SHAFT, INSTALL

1. Install the two half moon shaped thrust washers in the annular groove immediately behind the timing gear mounting flange on the auxiliary drive shaft.

2. Slide the shaft into the cylinder block, being careful not to damage either of the gears, until the two halves of the washer seat in the recess machined in the cylinder block and the end faces are located against the dowel, Fig. 19.

AUXILIARY DRIVE GEAR, INSTALL

1. Set engine crankshaft at top dead center on Nos. 1 and 6 cylinders, No. 1 being the compression stroke.
2. Turn the auxiliary drive shaft with a spanner wrench on the hex portion until the vertical slot in the injection pump drive hub coincides with the slot in the pump adapter plate.
3. With the engine set as described above, install the auxiliary drive gear and secure with retaining plate and bolts.
4. Install auxiliary drive gear cover.
5. Check backlash between all gears, Fig. 21. should be .003 to .006".

TIMING

As timing gears are employed on this engine, the factory setting remains constant. The resetting or checking of the timing can easily be carried out if the following instructions are kept in mind. *The removal of the cylinder head does not in any way affect the timing of the engine.*

Establishing T.D.C.

Top Dead Center for Nos. 1 and 6 cylinders may be established either by viewing the T.D.C. mark on the flywheel through the inspection hole provided in the flywheel housing or by removing the crankshaft nut washer and ensuring that the "V" groove on the front face of the crankshaft is vertical, Fig. 14.

To check or reset fuel injection pump timing, a timing pin is provided in the lower half of the timing case, arranged to locate in a drilled hole in the rear face of the crankshaft pulley, Fig. 22.

To establish T.D.C. on Nos. 1 and 6 cylinders, turn engine crankshaft in normal direction of rotation and unscrew the timing pin until it locates in the drilled hole in the rear face of the crankshaft pulley. *Under no circumstances should an attempt be made to turn the engine when the timing pin is engaged in the pulley or damage may result.*

Valve Timing

When the valve timing is set at the factory, certain marks are stamped on the timing gears, Fig. 23, so that the original setting may be obtained should the timing be disturbed for any reason.

There is no adjustment for valve timing. Should the timing be found to be incorrect, the gears can only be one or more teeth out of correct alignment.

Fuel Injection Pump Timing

When the fuel injection pump is removed, a machined slot will be noted in the hub of the worm gear on the pump shaft and a slot approximately 1/8" wide in the adapter plate will also be seen, Fig. 24.

Fig. 23 Timing marks on drive gears

Fig. 24 Timing slot on fuel injection pump adapter plate and drive hub

Fig. 25 Alignment marks on fuel injection pump and adapter plate

With these slots in alignment, and the crankshaft set at T.D.C. with No. 1 cylinder on the compression stroke, the fuel injection pump should be installed with the scribed line on its mounting flange coinciding with the line on the pump adapter plate, Fig. 25. Should the machined slots not be in alignment, adjustment may be made as follows:

1. Turn engine crankshaft in the normal direction of rotation until No. 1 cylinder is at T.D.C. on compression.
2. Remove auxiliary drive gear cover on timing case.
3. Remove three securing bolts and auxiliary drive gear.
4. Turn auxiliary drive shaft until the machined slots are in alignment.
5. Install auxiliary drive gear and secure in position, being sure that the drive shaft does not move during this operation.
6. Install drive gear cover on timing case.

Checking Fuel Injection Pump Timing

1. Remove pump inspection plate to expose the rotor.
2. Turn engine crankshaft in normal direction of rotation until scribed line marked "H" on pump rotor coincides with scribed line on snap ring, Fig. 26.
3. Check that the static timing on No. 1 cylinder is 29 degrees B.T.D.C. by measuring the appropriate distance on the flywheel rim (4.02") or by measuring the piston depth from T.D.C. which should be .399".
4. The three holes in the pump mounting flange are slotted for pump timing adjustment. This may be accomplished by releasing the securing nuts and turning the pump in the desired direction.

PISTONS & RODS

Removal

1. Remove cylinder head assembly.
2. Remove oil pan.
3. Turn engine crankshaft until two rod bearings are at bottom center, then remove self-locking nuts.
4. Remove caps, bearing shells and rod bolts.
5. Carbon ridges at top of cylinder bores should be removed before attempting to remove pistons.
6. Push pistons and rods out of top of cylinders.
7. Turn engine crankshaft until next two rods are at bottom center and repeat removal operation. Further turn crankshaft and remove the two remaining pistons and rods in like manner.
8. Pistons are numbered 1 to 6 beginning with No. 1 at front of engine. Rods and caps are also numbered to indicate the cylinder to which each is fitted.

Piston Pin Removal

1. Using internal snap ring pliers,

Fig. 26 Alignment marks on fuel injection pump rotor

remove rings from pistons.
2. The pins can then be pushed out if the pistons are heated in clean water to a temperature of 100 to 120 degrees F.

Connecting Rod Bushings

The bushings are a press fit in the rod. Use suitable tool to press out old bushing. Remove any sharp edges around bushing rod bore. Press in new bushing, being certain that oil hole in bushing coincides with hole in rod. Ream out new bushing to suit pin size being installed.

Piston & Rod, Assemble

Heat piston in clean water to a temperature of 100 to 120 degrees F. Then with the stamped mark "Front" on the piston crown facing toward you, place the rod in position, taking care to note that the number on the rod is to the left-hand side. Insert pin in position and install snap ring, making sure that it fits securely in piston groove.

If the original pistons are being re-used, they must be assembled to the same connecting rod: Piston marked "1" must go with rod marked "1", and so on. Use new snap rings even if the old ones appear not to be damaged or strained.

Piston Rings, Install

1. Wash rings to remove any grease or oil that may be present.
2. Check rings for correct end gap which must be the minimum limit listed in the specification table.
3. Install the new rings as directed in the container in which the rings are packed.
4. Rings must be arranged so that their gaps are equally spaced around the piston and not in line with one another.
5. When installing new rings to original pistons, clean out piston ring grooves, using an old ring from the appropriate groove for the purpose.
6. Examine piston skirt and if there is any scoring the piston must be discarded.
7. The piston must be examined carefully for damage to the ring grooves and to be sure that the rings move freely when installed.
8. *When installing new rings to worn cylinder sleeves, the ring gaps should be checked at a cylinder bore diameter of 3.875".*

Piston & Rod, Install

1. Before assembling rod to crankshaft, check to see that the word "Front" stamped on the piston crown is toward the front of the engine.
2. The piston, if correctly installed, will not protrude above the cylinder block head face more than .0096" or less than .0028".
3. When installing piston and rod assemblies in the engine, be sure that the side of the rod that is stamped with the number faces the camshaft side of the engine.

CYLINDER SLEEVES

The cylinder block contains renewable cast iron dry sleeves. Replacement sleeves are supplied unbored and must therefore be bored and honed to the finished dimensions after installation.

As the efficient running of a diesel engine is particularly dependent on good compression, the engine should be re-sleeved or re-bored to .030" oversize when the cylinder bores are worn to such an extent that engine performance is affected.

Fig. 27 Removing upper half of main bearing

Fig. 28 Aligning bridge to cylinder block face

Fig. 29 Installing bridge piece oil seals

Each cylinder bore should be checked with an inside-reading micrometer to determine taper, out-of-round or worn condition. If the bore wear does not exceed the limits of .002" out-of-round and .005" taper, new standard size service piston rings will give satisfactory performance provided the piston clearance is not excessive.

However, if the wear exceeds the limits, it is recommended that new sleeves be installed. Bore the new sleeves to approximately .003" of the required oversize diameter. This will allow enough stock for the final step of honing the bores so that the exact clearance may be obtained for the piston.

CRANKSHAFT & MAIN BEARINGS

Under normal circumstances, by the time the main bearings and thrust washers require replacing, the crankshaft will need to be removed for regrinding. However, if for any reason one or more bearings or thrust washers have to be replaced or removed for inspection, this can be accomplished without removing the crankshaft from engine.

1. To remove a main bearing, take off the cap of the bearing in question. *Where Nos. 1 and 7 main bearing caps are concerned, it is necessary to remove the front and rear main bearing bridge or filler block pieces before the bearing caps can be removed. The front bridge piece is secured to the block by two recessed slotted round-head capscrews, and the two lower timing case attaching bolts. The rear bridge is secured to the cylinder block by two recessed slotted round-head capscrews and the two lower rear main bearing oil seal housing attaching bolts.*
2. Do not remove more than one bearing cap at a time.
3. Loosen the remaining bearing cap bolts one or two turns.
4. Remove lower half of bearing from cap.
5. With a thin piece of wood, push out top half of bearing by rotating it on crankshaft, applying the tool to the opposite side of the bearing lip, Fig. 27. *Note that the locating lips on the bearing are on the camshaft side of the engine.*
6. Insert a new bearing half in the top, inserting the plain end first. Install new bearing half in cap.
7. Replace cap and tighten bolts lightly before proceeding with the next bearing.
8. Having replaced the bearings and caps, tighten the bolts to the torque specified in the Specifications table. Then lock with tab washers.
9. If the front and rear bridge pieces have been removed, lightly coat the metal-to-metal faces with sealing compound and refit them, ensuring that they are correctly aligned with the block face, Fig. 28. Install bridge piece oil seals, Fig. 29.

Crankshaft Thrust Washers

1. The thrust washers fit in recesses provided on either side of the center

main bearing housing and cap, Fig. 30. To renew them, remove center bearing cap.
2. Remove two bottom half washers from cap.
3. The two top half washers can be removed by sliding them around from one side with a piece of wood and rotating them until they can be removed.
4. To install new thrust washers, lightly coat the two upper halves with engine oil and slide them into the recesses provided. The steel side of the washers should be towards bearing housing.
5. Place the two lower halves on either side of bearing cap and replace cap.
6. Torque bearing caps to specifications.
7. Check crankshaft end play as shown in Fig. 31. End play should be within the limits listed in the Specifications table.

CRANKSHAFT REAR OIL SEAL

The oil seal housing consists of two halves bolted around the rear of the crankshaft. It has a spiral oil return groove recessed to a depth of .004 to .008″. The bore of the housing is machined to accommodate a rubber cored asbestos strip. The strip consists of two sections, one for each half of the oil seal housing. When installing the seal with the crankshaft in position, proceed as follows:

1. Place one half of housing in a vise with the seal recess uppermost.
2. Install seal in groove, leaving about 1″ of seal extending at each end. Be sure that each end of strip projects .010 to .020″ beyond half housing joint face. Allow middle of seal to bulge out of groove during this operation.
3. With thumb or finger, press remainder of strip into groove, working from the center. Then use any convenient round bar to further position the strip by rolling and pressing its inner diameter. This procedure takes advantage of the friction between the strip and the groove at the ends to compress the rope while being certain that the projections of the end faces of the rope remain as set.
4. Remove all traces of old gasket from cylinder block rear face and install a new gasket coated lightly with a suitable gasket compound.
5. Lightly paint the faces of the housing with a non-hardening gasket compound.
6. Spread a film of graphited grease over the exposed inside diameter surface of the seal face.
7. Assemble the half housing around the crankshaft rear journal and fasten together by two bolts.
8. Rotate complete seal housing on the shaft to position the strips, and to establish that the assembly turns easily on the shaft.
9. Bolt the seal housing in position on the block and rear main bearing cap bridge piece and tighten.

Fig. 30 Location of crankshaft thrust washers

Fig. 31 Checking crankshaft end play

Fig. 32 Oil pump and oil delivery housing

OIL PAN

1. Remove drain plug and drain oil.
2. Remove dipstick and tube, strainer, breather pipe and all bolts securing pan to crankcase.
3. Remove all traces of old gasket.
4. Wash and clean strainer.
5. Installation is made in the reverse order. Be sure that oil suction pipe enters the hole provided in the strainer.

OIL PUMP & OIL DELIVERY HOUSING

1. Remove oil pan and strainer.
2. Disconnect oil delivery housing from crankcase.
3. Unscrew oil pump locating bolt. *This bolt is located outside of cylinder block.*
4. Remove oil pump and oil delivery housing. *The two parts of the assembly are connected by a short pipe which is a push fit in each component, Fig. 32. A rubber "O" ring is recessed into the bore of both units to ensure an oil tight joint. It is advisable to replace these seals whenever the connecting pipe is disturbed.*
5. Reverse the foregoing to install.

Oil Pump Repairs

1. Remove bottom cover and disassemble pump by pulling out the shaft, inner and outer rotor.
2. Clean all parts and inspect rotor for cracks or scores.
3. Install rotors in pump body, making sure that chamfered edge of outer rotor enters pump body first.
4. Check clearance between the maximum diameter of inner rotor and minimum diameter of outer rotor at all points. If clearance exceeds .008″, renew oil pump.
5. Check clearance between top of rotors and surface of pump body with a feeler gauge and straightedge. If clearance exceeds .005″, renew oil pump.
6. Reassemble pump and install.

WATER PUMP

1. Drain cooling system and remove fan and belt.
2. Unfasten and remove pump from cylinder block. Pump must be withdrawn during removal of mounting bolts to permit removal of left-hand center bolt, Fig. 33.

Water Pump Repairs

1. Remove pulley with puller. Left-hand center mounting bolt may now be removed from housing if so desired.
2. Remove front bearing snap ring.
3. Press out shaft with bearings and spacer from rear (impeller) end.

   If the impeller is badly corroded so it cannot be removed from the shaft without damage, it can be removed with the shaft from the front end of the pump.
4. Remove impeller and rear seal from housing.
5. Remove front seal, retainer and flange.
6. Press two bearings and spacer from shaft.
7. Reverse disassembly procedure to

Fig. 34 Diesel fuel system with C.A.V. hydraulic governed injection pump

Fig. 33 Removing water pump pulley. Mounting bolt shown can be removed only after pulley is taken off

Fig. 35 Fuel supply pump

assemble the pump, noting the following:

8. Be sure that each bearing end cover faces outward toward front end of shaft.
9. The front seal retainer plate is "dished" and when positioned, the center of the plate must not be in contact with the bearing.
10. Install felt seal and retainer housing so that these bear on retaining plate.
11. Half fill space between bearings with wheel bearing grease and press complete assembly into pump housing from front end. Install front snap ring.
12. Install rear seal into housing with carbon face positioned toward rear. When installed, seal must rest squarely on its seat and not be misaligned in any way.
13. At this stage the shaft must be turned by hand to be sure that no undue resistance to rotation exists.
14. Insert left-hand center mounting bolt in housing, Fig. 33.
15. Install pulley and key, being sure no end play of shaft is incurred.
16. Press impeller on shaft so that a clearance of .012 to .019" clearance is present between inner edge of impeller vanes and pump body.

FUEL SYSTEM

Fuel Filter Maintenance

The first filter is a gauze type fitted in the fuel lift pump. It should be removed by unscrewing the bolt securing the domed cover on the top of the fuel lift pump and cleaned every 12,000 miles or 600 hours of operation unless the condition of the fuel warrants more regular attention. *When reassembling, be sure that a good seal is made between the cover and fuel pump body as any leakage of air here may cause air leaks in the fuel system.*

The second filter is a paper element type, the element being located between the top and bottom covers of the filter. The paper element should be renewed every 18,000 miles or 900 hours of operation.

Fuel Oil Filter, Replace

1. Unscrew the bolt in the center of the top filter cover.
2. Remove filter bottom cover.
3. Remove and discard element.
4. Clean filter top and bottom covers.
5. If gaskets are not in good condition, install new ones.
6. Reassemble fuel filter and bleed as follows:

Bleeding Fuel System

1. Referring to Fig. 34, loosen air vent screw on front of governor control cover (mechanical governor) or on top of control gear housing (hydraulic governor).
2. Loosen one of the two hydraulic head locking screws on the side of the fuel pump body.
3. Operate priming lever of fuel pump. When fuel, free of air bubbles, is expelled from each venting point, tighten the head locking screw first, then the governor vent screw.
4. Loosen pipe union nut at the pump inlet. Operate the priming device and retighten when fuel, free of air bubbles, is expelled from around threads.
5. Loosen the unions at the nozzle ends of two of the high pressure pipes.
6. Set engine speed control in the fully open position and be sure that the "Stop" control is in the "Run" position.
7. Turn engine until fuel oil, free from air bubbles, is expelled from both fuel pipes.
8. Tighten unions on fuel pipes.

FUEL SUPPLY PUMP

The fuel supply pump, Fig. 35, is of the diaphragm type similar to the type used on gasoline engines. It is located on the right side of the engine and driven by an eccentric cam on the camshaft.

A hand primer is an integral part of the fuel supply pump. Use the hand

primer to pump fuel from the tank until supply pump, filters, pipes and injection pump are filled with fuel.

Whenever an attempt is made to start a new or rebuilt engine or an engine on which fuel lines have been disconnected (such as when changing a fuel filter or servicing the injection pump) or an engine that has been standing idle for some time, the fuel system must be primed or bled. The procedure is given under Fuel Filter Maintenance.

FUEL INJECTION PUMP

The fuel injection pump which is shown being removed from the engine in Fig. 17, is a distributor type pump incorporating an all speed governor and an automatic advance. The pump is driven by a splined shaft. It is a self-contained, oil-tight unit, requiring no external lubricating system. The pump housing is completely filled with fuel oil under pressure during operation so that all parts are adequately lubricated.

Pressure maintained within the pump housing prevents the formation of air locks and also the entrance of dirt, water or other foreign matter which might impair the efficiency of the pump.

Pumping is effected by a single pumping element, having twin opposed plungers, located transversely into a central rotating member which also acts as a distributor, Fig. 36. The rotor revolves in a stationary member, known as the hydraulic head. The pump plungers are operated by contact with cam lobes on a stationary internal cam ring.

The fuel is metered before entering the pumping element, and the accurately metered high pressure charges are distributed to the engine cylinders in correct firing order and at the required timing intervals through a system of ports in the rotor and the hydraulic head.

Fig. 36 Fuel injunction pump rotor showing inlet and injector stroke

Fig. 37 Maximum fuel adjustment

A simple hydraulic type governor is embodied in the pump to give accurate control of engine speed throughout the complete speed range of the engine and under all conditions of engine loading. An automatic advance mechanism is also provided to vary the point of commencement of injection.

Maximum Fuel Adjustment

Maximum fuel adjustment is made by limiting the maximum outward travel of the pumping plungers at a point where the desired fueling is obtained.

The cam rollers (A), Fig. 37, are carried in shoes (B) against which the pumping plungers (D) are pressed by the incoming fuel. The shoes slide in guides machined in the rotor, and are retained in an endwise sense by top and bottom adjusting plates. "Ears" (F), integral with the roller shoes, project into eccentrically cut slots (G) in both adjusting plates. The "ears" are shaped to match the contour of the slots.

The bottom adjusting plate is rigidly clamped between the drive plate and the end of the rotor. The screws that secure the drive plate pass through elongated holes (E) in the adjusting plate so that the adjusting plates can be moved when the screws are loosened. Top and bottom plates are located one to the other by lugs integral with the top plate.

The plungers reach their outward limit of travel when the "ears" on the roller shoes contact the curved sides of the slots in the adjusting plates. In Fig. 37, the adjusting plates are shown in the position which would provide the lowest possible maximum fuel setting. Since the slots in the adjusting plates are eccentric, maximum plunger travel will be increased if the adjusting plates are moved in a clockwise direction in relation to the rotor. The movement provided permits a wide range of maximum fuel settings. Clearance (C) indicates the remaining travel to bring the plungers to the maximum fuel position.

Fig. 38 Fuel injection nozzle

Fig. 39 Nozzle valve and body removed from nozzle holder

Fuel Metering

Apart from the small losses which occur during the injection stroke, the total volume of fuel introduced into the element is passed on to the nozzle. Metering is effected, therefore, by regulating the volume of fuel which enters the element at each charging stroke.

The volume of the charge is governed by two principal factors: the fuel pressure at the inlet port, and the time available for fuel to flow into the element while the inlet ports in the rotor and the hydraulic head are in register. It is by controlling the pressure at the inlet port that accurate metering is achieved.

INJECTION PUMP REPAIRS

Disassembly, assembly, testing and adjustment of the pump are operations which demand the services of specially trained personnel and the use of certain special tools and test apparatus. Conditions of scrupulous cleanliness must be maintained in workshops where pump overhaul is carried out since even the smallest abrasive dust particles can cause damage to the pump, impair its efficiency and considerably shorten its satisfactory working life.

FUEL INJECTION NOZZLES

The performance of the high speed diesel engine depends largely on the proper function of its fuel injection system. For maximum efficiency it is essential that the engine be not only provided with metered amounts of fuel at exactly timed intervals, but also that it receives each charge of fuel in the proper condition so it can be completely consumed without causing smoke at the exhaust. This is the function of the fuel injection nozzle, Figs. 38 and 39.

The nozzle described here is of the closed type, so called because the nozzle closes of its own accord after each injection of fuel into the engine combustion chamber. The principal parts of the nozzle are the valve and the body, Fig. 39. The valve is a plunger accurately lapped into the nozzle body to the nearest fit within which it will work freely.

Fuel is fed to the mouth of the nozzle through small holes drilled vertically in the nozzle body, which terminate in an annular gallery above the valve seat. The nozzle valve is raised from its seat by pressure of fuel from the injection pump. The fuel in this small gallery is then forced through holes in the tip of the nozzle to form a spray in the combustion chamber.

Nozzle Maintenance

All nozzles should be removed from the engine at regular intervals. Just how long these intervals should be depends on the different conditions under which the engine will operate. Where ideal conditions of good combustion, adequate cooling and absolutely clean fuel are realized, the nozzles will need little attention. Since the efficiency of the nozzles vitally affects the performance and economical operation of the engine, no engine should be allowed to run with defective nozzles.

Testing Nozzles

If everything else is in order (see Trouble Shooting) and the nozzles are still suspected, the nozzle causing the trouble can often be found by releasing the pipe union nut on each nozzle in turn, with engine running and listening to the idling performance of each of the cylinders.

1. To test a doubtful nozzle, loosen injection pipe at both ends and remove nozzle holder from cylinder head. *A blast of compressed air around each nozzle before loosening the holder will prevent dirt or moisture from entering the combustion chamber when the nozzle is removed.*
2. Turn nozzle and holder around the injection pipe so that the nozzle points away from the engine.
3. Retighten both ends of injection line.
4. Next, loosen pipe unions at the other nozzles to prevent fuel oil from being sprayed into cylinders.
5. Turn engine with starter until the removed nozzle sprays fuel into the air. *If spray is "wet" or "streaky", or to one side, or if the nozzle "dribbles", remove and install a complete new or reconditioned unit. Keep hands away from spray as the working pressure will cause the oil to penetrate the skin with ease.*

Nozzle Repairs

Like injection pump repairs, nozzle repairs should be performed in a clean, dust-free place where no other work is performed, and the job should be done by specially trained personnel.

MODEL INDEX & ENGINE APPLICATION

ENGINE IDENTIFICATION—Reo service parts identification plate is located on inside of truck cab. Stamped on plate is the model of the engine, transmission, auxiliary transmission, rear axle and front axle. This represents only the equipment on the vehicle when shipped from the factory. Prior to Reo's assimilation by The White Motor Company, identification plates were attached to engines and transmissions.

①—When checked with a ½″ wide feeler it should require a 3 to 8 lb. pull on a spring scale to withdraw the feeler past the piston.
②—Front 3.1231–3.1238, others 3.1235–3.1242.

GENERATOR & REGULATOR SPECIFICATIONS

★To Polarize Generator: For internally grounded systems, disconnect field lead from regulator and momentarily flash this wire to regulator battery terminal. For externally grounded systems, connect a jumper wire from "hot" side of battery to armature terminal of generator.

*Camber may vary as much as ½° either way from the mean specifications listed.

†Kingpin inclination is built into the axle beam and should not be disturbed.

Engine Section

Fig. 1 Sectional view of Reo OA engines

CYLINDER HEAD, REPLACE

All Engines

When removing a cylinder head a chisel or screw driver should never be used to pry it loose from the cylinder block. Use an eyebolt in the third or fourth spark plug hole (6-cyl. engines), lifting up on the eyebolt while tapping lightly around the edges of the head with a lead or rawhide hammer or mallet. Be sure all the head stud nuts or bolts have been removed before starting to remove the head.

In replacing the head, the stud nuts or bolts at the center of the head should be tightened first and then work outward from side to side and to the ends. Draw the nuts or bolts down evenly until all are normally tight. After the engine has run long enough to warm it up, make a final tightening with a torque wrench to the torque loads given in the *Tune Up & Valve Specifications* table (Figs. 3,4).

V8 Service Note

Beginning with Engine No. 227579 (April 29, 1959) all V8 engines have been assembled with redesigned rocker arm covers and cylinder heads. Eight bosses were added to the head casting and are drilled and tapped for the cover hold-down bolts.

Important: The two studs in each head are positioned at the front and rear corners on the inner edge. *Studs must be used at these four points since the holes are drilled through into the water outlet passages.* If capscrews are used in these tapped holes, water will leak past the threads and into the rocker arm chambers. The other holes are not drilled through.

ROCKER ARM SERVICE

Sludge and gum formation in the rocker arms and shafts will restrict the normal flow of oil to the rocker arms and valves. Each time the rocker arm and shaft assemblies are removed they should be disassembled and thoroughly cleaned.

When disassembling rocker arms, place all parts on the work bench in their proper sequence to insure correct assembly.

Clean all sludge and gum formation from the inside and outside of the shaft. Clean oil holes and passages in the rocker arms and shafts. Clean the oil connector. Inspect the shafts for wear.

Check the ball ends of the rocker arms to be sure they are not pitted or rough. If used in this condition, it will be difficult to maintain valve clearances.

Six Cylinder Engines

The valve mechanism is pressure lubricated from the rear camshaft bearing up through an oil passage in rear of block, through slot in cylinder head gasket to passage in head, up to and into the rocker shaft at rear support. The two tubular shafts on which the rocker arms are mounted are held in position by two terminal and five intermediate supports using seven of the bolts that secure the cylinder head to the block. The five intermediate supports are alike, but the two end supports are closed on the outer face, against which one end of the rocker arm shaft is inserted.

Oil holes in the rocker arms are drilled at a 10° offset angle from vertical toward the valve end of the arm. The arm has a split type bronze bushing. Oil holes in the shaft are drilled at right angles to the centerline of the shaft at top and bottom.

When installing new bushings in arms, drill hole in bushing after installation using hole in rocker arm as a guide. Be sure and clean off all burrs on inner side of bushing caused by drilling. When installing rocker arm cover make certain the two leather washers (nut gaskets) are properly in place.

CAUTION: Tighten the holding nuts firmly but not to a point of springing the cover.

Fig. 3 Cylinder head tightening on OA, OH engines

Fig. 4 Cylinder head tightening sequence. Reo V8 engines

Rocker Arm Bushing Data

Rocker Arm I.D., Bushing O.D. (Press fit)	1.1245-1.1255
Bushing I.D., finish after assembly	.9903- .9913
Rocker Arm Shaft O.D.	.989 - .990
Nominal clearance	.0013-

NOTE: To facilitate assembly of bushing and rocker arm, coat back of bushing with a mixture of white lead and oil before pressing into place.

VALVES, ADJUST

All Engines

Adjust the valves to the clearances given in the *Tune Up & Valve Specifications* table. If the valves are to be adjusted warm, run the engine for about 30 minutes to normalize the expansion of all parts.

VALVES, REMOVE

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}$", otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the block or head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing the seats has a valve guide pilot.

The valve seat width after refacing should be a liberal $\frac{1}{16}$" for intake seats but not more than $\frac{3}{32}$" in any case. The width of exhaust seats should be $\frac{3}{64}$" to a liberal $\frac{1}{16}$".

A simple check can be made to prove the fit of the valve in the valve seats by spreading a thin film of Prussian Blue on the valve face and inserting the valve in the valve seat. With hand pressure, rotate the valve ¼ turn, remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer will indicate an inaccurate valve and valve seat refacing operation.

Fig. 2 Sectional view of Reo V8 engine

VALVE ROTATORS

Increased exhaust valve service in these engines is accomplished by the use of "Roto Valve" mechanism which is a special valve spring retainer and cap located on the end of the valve stem.

In operation, the rocker arm striking the cap lifts the retainer first, thus taking the spring load off the valve before lifting it from its seat. When the valve is in the raised position, it is free to rotate due to the vibration of the system.

When checking valve clearances, the feeler gauge is placed between the cap and socket as there is no other flat surface in the valve train.

VALVE SEAT INSERTS

Since these inserts are too hard to reface by ordinary hand grinding methods, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and the valve guide pilot is a snug fit in order to assure a concentric finish. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert (if a suitable puller is not available), drill two holes at opposite sides of the insert but not all the way through. Then cut through the undrilled portion with a sharp chisel and remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the new insert with "dry ice" to obtain maximum contraction of the metal and place it in the recess. If necessary, the insert may be pounded in by using a round driver the same size as the insert and pounding on same with a hammer.

If a standard insert is too loose, an oversize insert should be used. Oversize inserts are $\frac{1}{16}$" larger than the standard and, therefore, the recess should be bored out $\frac{1}{16}$" to accommodate the oversize insert.

When installed, peen the block or head

Fig. 5 Relationship of front end components. Reo V8 engines

around the insert bore to insure it remaining in place.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 4A. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16", and since the acceptable valve head margin is approximately 1/16" to 3/32", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, *the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.*

Fig. 4A Checking valve spring installed height

VALVE SPRING TESTING

After removing the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Tune Up & Valve Specifications* table within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should be scrapped.

VALVE GUIDES, REPLACE

Clean the valve guides with a wire guide brush and check the clearance between the valve stems and guides. Excessive clearance will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

To check valve stem-to-guide clearance, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance, it will be necessary to replace the valve guide.

If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

Valve stem-to-guide clearance may also be checked with a dial indicator or with plug gauges.

Valve guides may be removed and installed with a suitable puller and installer made for the purpose. If such equipment is not available, the old guides can be driven out or they can be pulled out by using a piece of pipe together with a long bolt and suitable washers.

After the new guides have been installed, they should be reamed to round out the holes and to provide adequate operating clearances.

VALVE LIFTERS

These engines are equipped with barrel type lifters which can be lifted out from above after taking out the push rods. With this construction the oil pan and camshaft need not be disturbed.

TIMING GEARS

Valve timing is correct when the timing gears are installed so that the timing marks on the gears are meshed. Fig. 5 illustrates the relationship of the parts on V8 engines.

CAMSHAFT & BEARINGS

Camshaft end play is controlled by a thrust plate just behind the camshaft gear. End play should be held to about .005″ and can be checked by forcing the shaft back to the limit of its end play and inserting a feeler gauge between the thrust plate and the front end of the shaft. If end play is excessive, install a new thrust plate.

On these engines, steel-backed, lead babbitt-lined split bearings are used.

PISTONS & RODS, REMOVE

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Before removing pistons, mark the pistons with a file on the inside of the skirt to indicate the bore from which each piston was removed and also its position in the bore with relation to the camshaft side of the engine. Connecting rods should also be suitably marked if they are not marked already.

Remove the connecting rod caps and push the assemblies out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. It is advisable to install caps on rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

If the pistons and rods have factory markings to indicate their position in the cylinders, assemble and install them according to these marks, or according to the marks made during removal if they were not otherwise marked, Fig. 6.

CYLINDER SLEEVES

Overhead Valve Engines

Whenever piston or ring installation is to be made, check cylinder sleeve bores for scores, out-of-round and taper. If out-of-round .006″ or more or if taper wear is .006″ or more, sleeve should be replaced. Reboring of sleeves and use of oversize pistons is not recommended. In many cases sleeves can be pulled out by hand to remove from block. When tight, do not drive out by pounding with metal objects as sleeves may be damaged or block distorted.

If rings only are to be installed, prior to removing pistons, remove ridge at top of each cylinder wall. When performing this operation, use particular care not to cut beyond the diameter of the cylinder wall. Leave approximately .001″ stock at ridge and remove with a hone. Each cylinder should be honed to break the glaze and to provide a better surface for wear-in of the new piston rings.

The cylinder block must be thoroughly cleaned after completion of honing operations.

Drain and dry out block surrounding sleeve area to prevent dripping or seepage of water on bearings. If engine is installed in stand RS-C356, rotating block so that crankshaft is vertical will materially aid in keeping any water or grit off bearing surfaces. If re-ringing is done with engine in chassis, breaking glaze may be omitted due to hazard of grit getting into bearing surfaces.

CAUTION: If engine is rotated to fully inverted position, make certain that any abnormally loose sleeves do not fall out of block.

With sleeves out of block, remove any rough external surfaces with emery cloth *from chamfers only* (above lower "O" ring area). Use only sandpaper to clean other adjacent surfaces of sleeve or block.

Fig. 6 Correct assembly of pistons and rods. V8 engines

IMPORTANT: Always install new neoprene sealing rings ("O" rings) whenever changing or reinstalling a sleeve. Be particularly careful that "O" rings are installed without a twist, otherwise a leak is likely to develop around "O" ring seam. Coat sealing rings with clean hydraulic fluid or glycerine before installing on sleeve. Be certain top counterbore in block for flange of sleeve is clean before attempting to insert sleeve. Clean the seal lands in block and coat with hydraulic fluid or glycerine before installing sleeve.

Install sleeve and seal assembly in its position in lower diameter of crankcase by allowing sleeve to find its own seat, then with hand pressure on top of flange rotate sleeve right and left and quickly push in place. *Do not force sleeve into block.*

When sleeve is seated check and make sure that top flange, extends .001″ to .005″ above block. If sleeve flange is below planed surface of block it will not be sealed and held in place by the cylinder head and gasket which may then allow water seepage into the cylinder bore.

Shims of .003″ and .006″ thickness are available with which sleeve protrusion may be corrected to the allowable tolerance as shown in the following table.

Recommended Schedule For Shim Installation

Height Measured	Add Shim	Height Above Deck
.001″ above deck	None	.001″
.000″ even	.003″	.003″
.001″ Below deck	.003″	.002″
.002″ Below deck	.006″	.004″
.003″ Below deck	.006″	.003″
.004″ Below deck	.006″	.002″
.005″ Below deck	.006″	.001″
.006″ Below deck	.003″ & .006″	.003″
.007″ Below deck	.003″ & .006″	.002″
.008″ Below deck	.003″ & .006″	.001″
.009″ Below deck	.006″ & .006″	.003″
.010″ Below deck	.006″ & .006″	.002″

Whenever a sleeve height is adjusted by the use of shims, the resulting protrusion should be within .002″ of that of the adjacent sleeves if possible.

PISTONS, REPLACE

Before a honing or boring operation is started, measure all new pistons with a micrometer at points 90 degrees away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is important that refinished cylinder bores are trued up to have not more than .0005″ out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at room temperature (70°) when the piston is checked for fit in the bore. Therefore, the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10° between the temperature of parts is sufficient to produce a variation of .0005″.

With the piston rings and pin removed and cylinder wall and piston dry and clean, insert the piston upside down in the bore. Use a feeler ½″ wide which is long enough to extend the full length of the piston. The thickness of the feeler should be the same as the clearance given in the *Pistons, Rings & Bearings* table. With the feeler hooked to a spring scale, a specified lb. pull (see table) should be required to pull the feeler past the piston.

PISTON RINGS, REPLACE

When new rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the diameter of the bore. This is done with a "Glazebuster" or a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is to be fitted. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

PISTON PINS, REPLACE

These pins are the floating type, being free to rotate in both the rod and piston bosses. The pins are prevented from rubbing against the cylinder wall by snap rings which fit in grooves in the piston bosses.

Pins should be selected that can be installed by pushing with the palm of the hand with the piston at normal room temperature. To make assembly easier, however, heat the piston in boiling water for sion of the metal and quickly insert pin.

ROD BEARINGS, REPLACE

Connecting rods are fitted with precision type bearings, held in position by locking lugs which fit into grooves cut in the rods and in the caps.

Bearing clearance may be checked with Plastigage, which is available at any auto parts jobber. Instructions for its use are furnished with the package.

Lacking Plastigage, use a piece of tough paper or shim stock ¾" square which measures about .0005" under the maximum allowable bearing clearance. Oil the shim on both sides ad lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap nuts to the torque given in the table.

The clearance is correct if the rod can be moved endwise when tapped lightly with a hammer. If the rod can be moved endwise by hand, clearance is too great. On the other hand, if the rod will not move when tapped lightly with a hammer, not enough clearance is present.

Service Note

In checking bearing clearance, the White Company recommends the use of virgin lead wire. With this method, apply a thin film of SAE 20 engine oil to the bearing to be checked and place a piece of the lead wire (⅜" long) on each end of the rod bearing crankpin, parallel to the centerline of the crankshaft Then install the rod cap, rotating the crankshaft through a 15° arc as the cap nuts are being tightened. When the caps have been tightened to normal tension, free up the bearing by turning the crankshaft through a 15° arc and remove the cap and wire. Measure the flattened wire with a micrometer, which will be the clearance of the bearing.

MAIN BEARINGS, REPLACE

Insert type main bearings are used and may be replaced without removing the crankshaft. Main bearings should be replaced in sets and under no circumstances should they be filed or otherwise altered in an attempt to affect an adjustment.

Plastigage may be used to check the fit of bearings and instructions for its use are furnished with the package. The White Company, however, recommends the use of virgin lead wire to check the fit of bearings. This method is described under *Rod Bearings, Replace.*

CRANKSHAFT END PLAY, ADJUST

Overhead Valve Engines

On six-cylinder engines crankshaft end thrust is taken up on the front main bearing. On early models it is controlled by flanges on the upper half only of this bearing. Later models have thrust flanges on upper and lower halves.

On V8 engines crankshaft end play is controlled by flanges on the rear main bearing.

A quick check of crankshaft end play can be made by anchoring a dial indicator to the chassis back of the radiator with the indicator on the front of the crankshaft pulley. Throwing the clutch in and out will cause a forward movement of the crankshaft to the extent of its end play. Using a piece of 2 x 4 wood ahead of the pulley, pry the crankshaft back (with foot off clutch pedal).

If check shows end play in excess of .012", immediate correction of the condition is absolutely necessary because if the engine is allowed to run with excessive end play it will destroy the highly polished face of the crankshaft against which the bearing thrust flanges ride. Ultimately, this polished surface will be scored to the extent that a new thrust bearing will wear out in a very few miles. When this condition is reached the only correction is a new crankshaft.

CRANKSHAFT OIL SEAL, REPLACE

Overhead Valve Sixes

To replace the rear oil seal it is necessary to remove flywheel, oil pan and oil pan rear arch.

Many cases of oil leakage at the rear of the engine are caused by seals being damaged before and during installation.

In handling this seal, be careful that the inner seal part is not touched by dirt from the hands. Inspect before installing. If it is the least bit dirty or has any grit on it, wash in oleum spirits before installing. Any slight piece of foreign material which might become imbedded in this seal will cause it to leak.

Make sure that the hub of the crankshaft which the seal contacts is absolutely clean, polished and not scored. Invariable when the flywheel is removed, the edge of the crankshaft hub is burred or scratched when freed from the recess where it sets into the flywheel. Be sure and remove all burrs on hub and hub chamfer, eliminating all sharp and jagged edges before fitting seal over crankshaft hub.

As the seal is an expanding fit, be particularly careful not to distort or break the edge when fitting it over the crankshaft hub.

Secure housing or retainer to block from rear with 4 cap screws and tighten. Install rear arch. Secure retainer to arch from front with 3 lower and 2 upper cap screws. First secure all cap screws finger tight. Tighten screws top to opposite bottom alternately. Tighten lower center last.

The rear oil seal lip should be coated with grease (not oil) prior to installation on the crankshaft hub. The grease should be applied to the hub as well as the seal lip in order to avoid wiping the lubricant off the hub when the seal is installed. The purpose of this procedure is to prevent the seal from running with insufficient lubrication and, therefore, becoming excessively hot before crankcase oil can reach it. This grease application will also facilitate sliding the seal over the hub. Use Lubriplate #320, or an equivalent which has a relatively high melting point.

When bolting the housing into place, put Permatex #2 in the cap screw holes to keep internal pressure from forcing oil out between the cap screw and hole threads.

V8 Engines

Oil sealing at the rear main bearing is controlled by a wick-type seal in the same manner as for some side valve engines outlined above.

OIL PUMP REPAIRS

Oil pump is of the rotary type and is assembled to a special machined boss inside the crankcase. As the two rotors are matched at the time of assembly a complete new unit must be installed as rotor repairs are never satisfactory.

Oil pump drive gear is driven from the gear on the camshaft. The gear is pinned to the pump shaft and is replaceable.

WATER PUMP REPAIRS

These engines are equipped with ball bearing pump similar to that used on GC engines. A spring-loaded bellows type carbon seal is used and the shaft is retained by two ball bearings.

In servicing this pump, follow a similar procedure outlined above for GC engines.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

Fig. 7 Ignition details. Reo V8 engines

CARTER BBR2 CARBURETOR

Model 779S

In this carburetor, Fig. 8, correct air-fuel ratio is provided by a "balance tube" in the air horn. The balance tube should be checked each time the carburetor is serviced to see that the passage is open. The object of a balanced carburetor is to provide a constant air-fuel ratio regardless of size, type or condition of the air cleaner. Should the cleaner become clogged, the capacity will be reduced but the air-fuel mixture ratio will not be changed.

Service Note

Excessive richness above 50 mph may be caused by a clogged main vent tube. After removal of the rivet plug beneath the float bowl (use Tool T109-43) the main vent tube can be removed and a new tube inserted with Tool T109-195. Care must be exercised in inserting the new tube which must seat tightly. Use a new rivet to complete the installation.

Idle Adjustment

If the engine stalls while idling, set the throttle lever adjusting screw so the engine does not idle below 450 rpm. Then set the idle adjustment screw from ¾ to 1¼ turns open. If these adjustments do not correct the trouble, remove the idle orifice tube and plug assembly. Clean the tube passages with compressed air.

Float Setting

If the carburetor loads up after considerable service, check the float level as shown in Fig. 9 to a distance of $\frac{5}{64}$". Wear on the lip of the float lever will raise the float level. Before adjusting the float, be sure the float lever pin is firmly seated. Reset the float level by bending the lip of the float away from the needle to raise the level, or bend the lip toward the needle to lower the float level. Bend the vertical lip of the float only.

Pump Adjustment

If acceleration is not satisfactory, remove the pump jet and clean with compressed air. However, it is usually advisable to replace the pump jet as its cost is nominal. All jets must be seated gasoline tight. Poor acceleration may be due to damaged or worn plunger leather in the accelerating pump, sediment in the pump cylinder or clogged intake ball check at the bottom of the pump cylinder and discharge ball check in the discharge passage. If the plunger is removed from the cylinder, use care in installing to avoid damage to the plunger leather.

To adjust the pump, remove the air horn assembly, back out the throttle adjusting screw, and place the pump operating link in the center hole of the throttle shaft arm. Place Pump Travel Gauge T109-117S on the edge of the bowl cover so that the lip of the gauge extends over the top of the plunger shaft. Turn the knurled nut of the gauge until the lip contacts the plunger shaft at the

Fig. 9 Float setting. Carter BBR2 carburetor

Fig. 8 Carter BBR2 carburetor. Reo OA-255 engine

closed and wide open throttle positions. The difference in readings obtained at closed and wide open throttle positions should be "30" (30/64") plunger travel. Adjustments can be made by bending the horizontal portion of the pump lifter link.

The pump stroke is adjustable for high or low temperature. Set to the long stroke for cold weather and short stroke for hot weather driving.

CARTER WA1-2542S

Idle Choke Settings

Set idle mixture adjusting screw 1¼ to 2¾ turns open. For richer mixture turn screw out. Do not idle engine below 500 rpm.

Set automatic choke two points lean.

Float Level Adjustment

The distance from the float (at free end) to tip on lower edge of float chamber cover when needle is seated should be ½".

Pump Adjustment

With throttle valve seated, and connector link in upper hole (long stroke) the pump plunger should travel 13/32" from closed to wide open throttle position. Adjust by bending throttle connector rod at the lower angle.

Metering Rod Adjustment

This setting must be made after the pump adjustment or when leaner than standard rod is installed.

Insert Gauge T-109-102 in place of metering rod, seating tapered end of gauge in metering rod jet. Hold gauge vertical to insure seating in jet. With throttle valve seated, press down on piston link directly over piston until it contacts pump arm. There should now be less than .005" clearance between metering rod pin and shoulder in notch in gauge. Gauge must not drag on pin. Adjust by bending lip on piston link. Remove gauge and install metering rod, disc, pin and spring.

Anti-Percolator Adjustment

Open throttle valve .016" by placing drill or Gauge T109-44 between throttle valve and bore of carburetor (side opposite idle port). Bend rocker arm until there is a clearance of .010" between rocker arm lip and pump arm.

Fast Idle Adjustment

With fast idle cam in normal idle position, tighten throttle lever adjusting screw until it just seats against cam. Hold throttle lever closed and pull cam back until first (or lower) step is against (not on) set screw. There should now be ⅝" clearance between inside wall of air horn and lower edge of choke valve. Adjust by bending fast idle link at offset portion.

Fig. 10 Float level adjustment. Carter WCFB

Fig. 11 Pump adjustment. Carter WCFB

Fig. 12 Metering rod adjustment. Carter WCFB

Unloader Adjustment

With throttle valve wide open there should be $\frac{9}{16}$" clearance between lower edge of choke valve and inner wall of air horn. Adjust by bending cam on throttle lever.

CARTER WCFB-2220S, 2265S, 2563S, 2563SA

Idle and Choke Settings

Set idle mixture adjusting screws ¾ to 1¾ (1½ to 2½ on 2220) turns open. For richer mixture turn screws out.

Set automatic choke on "Index" mark.

Float Adjustments, Fig. 10

Vertical Adjustment—With bowl cover assembly inverted and bowl cover gasket removed, check the vertical distance from top of float to cover casting. This distance should be $\frac{3}{16}$". Adjust by bending float arms.

Float Drop Adjustment — With bowl cover assembly held in upright position, check distance between center of floats and bowl cover casting (gasket removed). This distance should measure ½" (plus or minus $\frac{1}{16}$"). Adjust by bending stop tabs on float brackets.

Lateral Adjustment—With metering rods removed, slide the cover assembly into position on the bowl casting. Note any interference between floats and carburetor bowl. If any interference exists, adjust by bending float arms.

Pump Adjustment, Fig. 11

Remove the dust cover from the bowl cover. Back out the fast idle screw and lever set screw until throttle valves seat in bores. With throttle valves seated, the flat on the top of the pump arm should be parallel with the top of the dust cover mounting boss. Adjust by bending the throttle connector rod at lower end. Pump connector link must be in outer hole in pump arm.

Metering Rod Adjustment, Fig. 12

This adjustment must always be made after the pump adjustment.

With the idle stop screw backed out and throttle fully closed, loosen the clamp screw on metering rod arm. Then press on vacumeter link until metering rods bottom in bowl. While holding metering rods down and throttle closed, rotate metering rod lift arm until finger on arm contacts lip of vacumeter link and tighten clamp screw in this position.

Vapor Vent Adjustment

This adjustment is to be made after the pump and metering rod adjustments.

With the dust cover and gasket installed and throttle valves wide open, there should be approximately $\frac{1}{16}$" clearance between the lower edge of the vent valve and dust cover. Adjust by removing the dust cover and bending the vapor vent arm.

Fig. 13 Holley 852-FFG carburetor

HOLLEY 852-FFG

These carburetors are dual downdraft units incorporating an integral governor. The governor throttle mechanism is part of the carburetor and has been designed to provide the needed power required for moving the throttle to governing speeds as controlled by a separately driven governor rotor. The combination of these two units give instant response and accurate governing.

The carburetor and governor can be cleaned and serviced with ordinary tools and the governor rotor can be serviced independent of the carburetor. *Do not under any circumstances apply compressed air to an assembled carburetor as to do so may rupture the governor diaphragm.*

Fuel & Float Level

When checking the fuel level in an open vessel, under 5 lbs. pump pressure the level should measure $\frac{23}{32}$". The measurement is taken below the surface of the float chamber cover (gasket in place) to the level of the fuel. The level may be corrected by bending the float arm, Fig. 13.

The float level can be set when the air horn is off by gauging the distance between the bottom of the float and the flange surface of the air horn, Fig. 14. Holding the air horn upside down and the float in the closed position, measure the distance from the flange surface of the air horn to what would normally be the bottom side of the float (not the soldered seam). The correct distance should measure $1\frac{11}{32}$". Bend the float lever arm as required to correct the float level.

Idle Mixture

The idle mixture is controlled by the idle adjustment needles. Turning these needles in makes a leaner mixture and turning them out makes the mixture richer. Turn the needles in until they just touch the seats and back off one full turn.

When the engine has warmed up to operating temperature, alter the adjustment as required to obtain smooth performance. The range should be between 1 and 1½ turns.

Accelerating Pump

The quantity of the fuel discharged by the accelerating pump can be controlled by changing the position of the pump link in the throttle lever. Of the three different positions (marked 1, 2 and 3) number 2 is the average setting, number 1 is for summer and 3 is for winter operation.

ZENITH SERIES 28, 29

Float Setting, Fig. 16

Float setting should be checked by holding the cover assembly upside down. With the weight of the float holding the needle valve seated, the distance from the far side of the float of the housing should be as given below:

28 Series	1½"
29W14	$1\frac{5}{16}$"
29W16	$1\frac{45}{64}$"

Idle Adjustment

For a preliminary adjustment, turn the needle into its seat and open one full turn. Run the engine until it reaches operating temperature and alter the adjustment as required to obtain smooth performance. The range should be 1 to 1½ turns open.

Accelerator Pump

This adjustment is provided in the form of three grooves on the pump piston rod. The carburetor must be opened up and the vacuum pump piston assembly removed. Compress the spring toward the vacuum piston to permit moving the pump rod to the outer end of the slot in the pump piston base. At this point the slot is wide enough to permit removal of the rod.

There are three grooves near the end of the pump rod providing for three lengths of pump stroke. Install the pump piston in the groove nearest the end of the rod to obtain minimum or half stroke; center groove for intermediate stroke and in third groove for maximum stroke. The spring holds the rod in the center of the pump piston base.

CARBURETOR GOVERNOR

King-Seeley

This governor, Fig. 17, is mounted between the caburetor and intake manifold and automatically governs the maximum speed at which the engine may be operated.

The gas mixture rushing from the carburetor through the governor throat strikes the offset throttle valve and tends to draw it closed. This action is opposed by a governor spring which is attached to the valve shaft through a cam ribbon and cam. By adjusting the pull of this spring, the governor valve may be made to remain open, and then closed at a predetermined engine speed. Adjustment of the spring pull is accomplished by changing the number of coils operating.

Fig. 14 Float setting. Holley 852-FFG carburetor

Fig. 15 Zenith 28 series carburetor

Fig. 17 King-Seeley (Handy) velocity type carburetor governor

Fig. 16 Zenith carburetor float settings

Fig. 18 King-Seeley governor adjustment

Adjustment

All governors are calibrated and adjusted in assembly to insure accurate control of the maximum engine speed of the model vehicle for which it is intended. However, there will be occasions when minor adjustments are required to satisfy local conditions where the truck is operating.

To adjust a governor for higher speed, turn the adjusting cap counter-clockwise or to the left; for lower speeds turn the cap to the right or clockwise. One turn on the adjusting screw will change the speed 300-400 rpm or between 4 and 5 mph.

When a more sensitive regulation is desired or if the governor is too sensitive and inclined to surge, correct the adjustment as follows by means of the calibrating nut shown at "A", Fig. 18.

If Governor is too Sensitive—If the governor is too sensitive or on the point of surging, remove the adjusting cap and hexagonal shaft assembly and place the special hollow wrench (A-24283) in position on nut "A". Insert the special adjusting wrench (A-25264) through this wrench and turn the main adjusting screw "B" to the right one turn. (These wrenches are available at King-Seeley Distributors.) With the hollow wrench in the slot of nut "A", turn this nut to the right about ¼ turn. The main adjusting screw "B" must be kept from turning while nut "A" is adjusted.

Holley Model 1174

Used with Holley carburetors, this governor, Fig. 19, is a vacuum controlled device featuring all the advantages of a mechanical governor without lengthy and complicated linkage. Should it become necessary to make any changes, proceed as follows:

To adjust the governor cut-off speed, remove the seal from the screw on the side of the governor housing and remove the screw. Rotate the engine until the end of the governor rotor, which carries the adjusting screw, is in line with the hole from which the screw was removed. Turn the adjusting screw clockwise to increase or counter-clockwise to decrease governed speed.

Whenever the governor has been disassembled and serviced, after reassembling turn the adjusting screw clockwise until it stops, then turn it counter-clockwise three full turns. Final adjustment is then made after the governor has been assembled to the engine.

The vacuum adjusting screw, Fig. 20, regulates the rpm spread between the governor full load cut-off speed and the no-load engine speed. Turning the screw clockwise will decrease the rpm spread. Turning it counter-clockwise will increase the spread. Changing the position of the screw will change the average governor speed and this should be corrected by the rotor adjusting screw.

ENSIGN LPG CARBURETOR

Model XG

This unit, Fig. 21, is known as a straight through carburetor, having a built-in economizer and easy starting feature. The economizer automatically produces a rich power mixture for high engine loads and a lean economy mixture for part throttle operation. The easy starting feature provides a separate set of air-gas orifices which produce a more positive mixture for starting only. This mechanism will be wide open or completely closed; it is not intended to function at intermediate speeds.

In operation, air enters the carburetor at slightly below atmospheric pressure as controlled by the regulating unit. Gas flows through the carburetor nozzles, into the venturi and is regulated by the main gas load adjusting screw. Air entering the carburetor air horn mixes with gas in the venturi before passing into the inlet manifold. The throttle disc controls the volume of combustible mixtures entering the engine, hence also controls engine speed and power.

Adjustments

1. Set the starting screw 2½ turns open.
2. Set load adjusting screw 6½ turns open.
3. Set idle adjustment screw (on regulator) 2 turns open.
4. Close the choke.

Fig. 23 Ensign gas economizer used on KGL carburetor

5. Open throttle at least halfway.
6. Crank the engine.
7. When engine starts, adjust starting adjustment first for maximum engine speed, then richer until speed drops slightly. Tighten lock nut.
8. Open choke and close throttle simultaneously.
9. Make temporary adjustment of load screw for highest rpm, holding throttle at about two-thirds rated speed (2400 rpm).
10. With engine warm, set idle stop screw for correct idle speed (450 rpm) and adjust idle screw for best idle.

Setting Load Screw With Analyser

Open throttle wide and load engine to obtain an engine speed of from ½ to maximum operating speed (1700-3400 rpm). Keep speed below any governor action. Set the load screw to give a reading of 12.8 on a gasoline scale or 14.3 on an analyser with an LPG scale.

To check the part throttle analyser reading, a vacuum gauge should be used. With engine under load, set the throttle to give a manifold vacuum of 10 to 13 at similar speed to previous check. The analyser should then read 13.8 to 14.5

gasoline scale or 14.9 to 15.5 on LPG scale.

Recheck idle adjustment (12 to 12.8 gasoline scale or 13.5 to 14.2 LPG scale) or best idle.

Setting Load Screw Without Analyser

Open the throttle wide and load the engine to obtain an engine speed of ½ maximum operating speed (1700 rmp), keeping speed below any governor action. Find the two load screw settings where the engine speed begins to drop, when going richer and leaner, and set at the mid-point. Recheck the idle.

Setting Load Screw Without Load

A reasonable adjustment can be made when it is not possible to place a load on the engine as follows: Disconnect economizer and plug intake manifold connection. Bring the engine to high speed. Adjust load screw to maximum rpm, then carefully screw in to a point where the rpm just begins to fall. Set the screw to the mid-point of these two positions and tighten lock nut. The idle adjustment must be carefully made before using this method as it influences the mixture under this engine condition.

Model KGL

This unit, Fig. 22, is similar in design to the XG unit except that it has an adjustable economizer instead of the fixed orifice type used on the XG unit. Note that the KGL model is equipped with a long, detachable throttle body.

Fig. 22 illustrates the complete carburetor in running position. To start, the choke disc is closed, cam lever closing the main orifice. Air is drawn through the orifice in the choke disc and gas is drawn through the orifice at the starting adjusting screw position. This starting gas mixture is adjusted with the starting adjusting screw which should then be locked when best position is found.

The choke lever is used in changing from starting to running position.

The load adjustment regulates the passage of gas through the main fuel orifice When once properly adjusted, the load adjusting screw should be locked in position.

On the carburetor used by Reo the load adjustment screw is replaced by a Gas Economizer assembly and the adjustment is made by turning the entire assembly in or out, Fig. 23.

The gas inlet is connected to the gas outlet of the Ensign fuel regulator or butane regulator unit. The "balance line" connection on the carburetor to a point on the fuel regulator compensates for increased air cleaner resistance, thereby maintaining a correct mixture over the entire engine operating range.

Gas Economizer

The gas economizer, Fig. 23, is an attachment to the carburetor utilized for the purpose of decreasing fuel consumption. This is accomplished by using the engine vacuum to automatically reduce the flow of fuel through the main fuel orifice whenever the engine is operating at less than 80% of full power. It regulates the flow of gas through the main fuel orifice by varying the size of the opening as the engine vacuum fluctuates with power demand.

The economizer is disassembled by removing the five cover screws. The body assembly is made up permanently and cannot be taken apart. It should be cleaned of any oil or dirt that may be present.

The only part that may need replacing is the diaphragm. When assembling be sure the diaphragm connecting bar is engaged in the groove in the adjusting screw.

Carefully check vacuum control connections to economizer for air leaks.

KGL Adjustments
Preliminary Idle Adjustment

Screw the idle adjustment in (for lean) or out (for rich) until a good smooth idle is obtained. This may be checked by means of manifold vacuum; the best idle is at the highest vacuum.

Power Adjustment

The power settings are for average operating conditions but may in some cases require a slight readjustment. With economizer adjustment screwed all the way in, adjust for best power at full throttle. Shorting out all but two cylinders will give about the right rpm for full throttle while making this adjustment. (If engine is equipped with governor it may be necessary to short out all but one cylinder to insure full throttle opening.) Loosen the lock screw on the dial and rotate the adjustment dial clockwise for rich, and counter-clockwise for lean. The correct adjustment for maximum power will be found at a point where rpm is the highest. If an exhaust analyser is used, meter should read approximately 13 to 1 at highest rpm.

Economizer

Remove short-out wires so all cylinders are firing. With no load on engine, open throttle until rpm is ¼ to ½ rated rpm (3350 rpm). Turn out economizer screw gradually until engine has reached peak rpm at this throttle setting and begins to slow down. Then turn screw back in until peak rpm is resumed and tighten lock nut. The throttle should be set by the throttle stop screw so that the throttle opening is constant. This setting will give good economy.

If the adjustment is screwed out too far the cruising mixture will be too lean for efficient operation. However, if this setting is too rich, poor economy will result.

Final Idle Adjustment

With main jet and economizer set as above, adjust the idle screw for best and smoothest idle. The throttle stop screw is set for desired idle rpm (450). Making this final idle adjustment will not affect the power and economizer settings.

Clutch, Transmission & Rear Axles

For Clark, Fuller, New Process, Reomatic, Spicer and Warner transmissions used on Reo trucks, see the "name" chapter for service procedures and lubricant capacities

For Eaton and Timken (Rockwell) driving axles used on Reo trucks, see the "name" chapters for service procedures and lubricant capacities

BORG & BECK

These clutches, Fig. 1, are single plate, dry disc types with no internal provision for adjustment for wear. However, each release lever is adjusted individually to the correct height, and no attempt should be made to adjust these levers unless the clutch is to be dismantled for overhaul. Overhauling the clutch should not be attempted unless a clutch rebuilder is available. Lacking this equipment it is recommended that the clutch cover and pressure plate assembly be exchanged for a rebuilt unit.

Fig. 1 Borg and Beck clutch

Clutch Pedal, Adjust

The general procedure for adjusting the clutch pedal is to shift the pedal down away from the toe board until the clearance or free movement is ¾" to 1". The pedal pad should come in contact with the toe board when the pedal is pressed down. If it does not move that far, making it necessary to spring the pedal to make the pad touch the toe board, shift the pedal down a little more.

Press the pedal down and note the distance the release bearing travels after it comes in contact with the release levers. To obtain a clean release the levers should be pushed toward the flywheel $\frac{7}{16}$". If it does not travel this distance shift the pedal up, bearing in mind that the pedal pad must touch the toe board as above.

Clutch Assembly, Replace

After removing the transmission, but before removing the clutch, mark with a punch the flywheel, clutch cover and pressure plate so that these parts may be assembled in their same relative positions and in the same position on the flywheel if the same clutch is to be reinstalled. This is important because they are balanced as an assembly.

To remove the clutch, pull out the clutch release bearing and sleeve. Unfasten the clutch cover from the flywheel, loosening each cap screw a few turns in succession until the cover is free. The clutch assembly and driven disc can then be removed from the flywheel.

When installing the clutch, coat the pilot bearing in the end of the crankshaft with wheel bearing grease. Clean the surfaces of the flywheel and pressure plate, making certain no oil or grease remains on these parts. Hold the cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the pilot bearing in the crankshaft. Bolt the clutch cover loosely to the flywheel, being sure the punch marks previously made are lined up. To avoid distortion of the clutch cover, tighten the cover bolts a few turns each in progression until all are tight. Guide the transmission into place, using care to see that the driven disc is not bent. Use a floor jack to support the transmission so that the clutch shaft may be guided through the driven disc safely. Adjust the clutch pedal free travel.

LONG CF

This type clutch, Figs. 2 and 3, employs centrifugal force to increase the pressure against the pressure plate and clutch plate at higher speeds, in addition to using conventional spring pressure. The release levers are provided with small centrifugal weights which are integral parts of the levers. As the clutch rotates at high speeds, these heavy ends of the levers tend to move outward and exert additional pressure against the pressure plate.

Clutch Control, Adjust

Unless the clutch control linkage is removed, the only adjusment is the length of the clutch release rod or rods. Before any adjustments are made, first make certain that the pedal shaft and throwout shaft operate freely. The pedal shaft is equipped with bushings and lubricated through grease fittings in the bearing housings. The throwout shaft

Fig. 2 Cutaway of Long CF semi-centrifugal clutch

Fig. 3. Layout of Long CF clutch parts

operates in the clutch housing with grease fittings in the clutch housing.

This rod ajustment is made to obtain proper clearance and thus compensate for normal lining wear. With the foot pedal in its normal raised position, the length of the rod or rods is adjusted to obtain a minimum of $\frac{1}{16}''$ free movement between the working face of the clutch throwout bearing and the clutch release levers. This will represent a free movement of the clutch pedal of about $1\frac{1}{2}''$. Lengthen or shorten the rod or rods to maintain free play at the pedal to insure $\frac{1}{16}''$ clearance at the throwout bearing.

Clutch, Replace

When removing the clutch assembly, after removing the transmission, care should be taken to back out the six attaching screws about three turns at a time successively. This will prevent the clutch cover from being distorted by permitting the tension of the clutch pressure springs to be held by two or three screws.

Do not permit the weight of the transmission to hang on the driven disc for if it is bent it will necessitate excessive pedal travel to release the clutch.

Upon installing, always use a pilot shaft through the driven disc. When assembling the clutch to the flywheel, turn all attaching screws in finger tight. Then tighten each screw with a wrench not over two turns at a time. Go from one side of the clutch to the other until all attaching screws are tightened securely.

Clutch Service

The three release levers are properly set in a parallel plane and permanently locked at assembly. They will require no further attention during the life of the clutch, and they cannot be serviced. The pressure springs are set on asbestos base insulator washers where they rest on the pressure plate.

LIPE-ROLLWAY TYPE ML

This clutch, Fig. 4, is a single plate, dry disc type in which pressure on the driven disc is provided by a heavy spiral spring acting through 20 interlocked levers.

Clutch Adjustment

The original setting of the clutch provides for $1\frac{1}{2}''$ free movement of the clutch pedal. As the facings wear the clutch sleeve moves toward the clutch release bearing, reducing the clearance and automatically cutting down on the free travel of the clutch pedal. When this travel drops to about $\frac{1}{2}''$, the clutch should be readjusted.

Never wait for the clutch to start slipping before adjusting it. It may then be too late to make an adjustment. Clutch facings quickly disintegrate once they become burned through slippage, and both the facings and pressure plate are short lived thereafter.

Do not adjust the clutch pedal linkage until the clutch has been adjusted to the correct Dimension "A", Fig. 5. The correct Dimension "A" for the clutches used are as follows. *Clutches may be identified by the manufacturers' number stamped on a name plate or on the cover or flywheel ring.*

Clutch No.	Dimension "A"	Shims Req. [1]
Z30s	1″	6
Z32s	$1\frac{1}{16}''$	6

[1] Removal of one shim .015″ thick is equivalent to reducing Dimension "A", by $\frac{3}{32}''$. The number of shims listed for each clutch should be placed under each strap when overhauling the clutch.

1. To adjust the clutch, block the clutch pedal in the depressed position. This is important, otherwise the straps and studs may become bent.
2. Back off adjusting nuts five full turns.
3. Remove pedal block. This will allow the adjusting plate to move out of contact with the adjusting shims.
4. Remove a sufficient number of shims to obtain Dimension "A". It is usually sufficient to remove only

Fig. 4 Lipe-Rollway clutch

Fig. 6 Removing clutch adjusting shims

one shim from each stud, Fig. 6, then checking Dimension "A" before removing more. *Be sure no portion of the shim is torn and remains under the flange of the adjusting plate and that an equal number of shims remain under each strap.*

5. Reblock the clutch pedal. This moves the adjusting plate into contact with the adjusting shims. Then tighten each adjusting strap nut firmly.
6. Recheck Dimension "A".
7. After the correct Dimension "A" has been established, adjust the vehicle clutch release linkage so as to obtain proper release bearing clearance or 1/8" to 5/32".

Clutch Driven Disc, Replace

1. After removing the transmission remove the cap screws holding the clutch to the flywheel and remove the clutch and driven disc.
2. Remove the flywheel ring stud nuts and adjusting straps one at a time and place the correct number of shims (see table above) under each strap.
3. Examine flywheel, making sure friction face is clean, smooth and dry.
4. Check release bearing and pilot bearing to make sure they are in good condition. Both these bearings are factory sealed and require no further lubrication.
5. Install a new driven disc and bolt the clutch to the flywheel, using a spare splined shaft to align the disc. When bolting the flywheel, screw in each bolt until it just contacts the cover plate, then gradually tighten alternate bolts until the clutch is drawn up evenly against the flywheel. Tighten remaining clutch-to-flywheel bolts.
6. After clutch is installed, check for proper release. Adjust clutch and pedal linkage as outlined above.

Pressure Plate, Replace

A pressure plate dished in excess of .015" or badly scored should be replaced with a new part. After removing the transmission and the clutch from the flywheel, proceed as follows:

1. Place clutch on arbor press with pressure plate down and compress spring as far as possible.
2. Remove four retractor springs after first removing pins.
3. Slowly release arbor press, allowing clutch spring to return to normal position.
4. Holding clutch assembly together by hand, turn it over and carefully lift off pressure plate.
5. Install new pressure plate, turn clutch assembly over and compress in arbor press.
6. See that retractor springs are in place and install pins.
7. Remove clutch from press and reinstall on flywheel.

ROCKFORD TYPE TT

This clutch is of the single plate dry disc type, Fig. 7, consisting of a pressure plate and cover assembly having 12 release springs, three release levers and a spring-cushioned driven disc mounted on a splined hub. There is no internal provision for adjusting the clutch but each release lever is adjusted individually to the correct height. No attempt should be made to adjust these levers unless the clutch is to be dismantled for overhaul. Overhauling the clutch should not be attempted unless a clutch rebuilder is available. Lacking this equipment, it is recommended that the clutch cover and pressure plate assembly be exchanged for a rebuilt unit.

Clutch Assembly, Replace

Before removing the clutch from the flywheel, punch mark the flywheel, clutch cover and pressure plate so that these parts may be assembled in their same relative positions and in the same position on the flywheel if the same clutch is to be reinstalled. This is important because they are balanced as an assembly.

After removing the transmission, pull out the clutch release bearing and sleeve. Unfasten the clutch cover from the flywheel, loosening each cap screw a few turns in succession until the cover is free. The clutch and driven disc can then be removed from the flywheel.

When installing the clutch, coat the pilot bearing in the end of the crankshaft with wheel bearing grease. Clean the surfaces of the flywheel and pressure plate, making certain no oil or grease remains on these parts. Hold the cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the pilot bearing in the crankshaft. Bolt the clutch cover loosely to the flywheel, being sure the punch marks previously made are lined up. To avoid distortion of the clutch cover, tighten the cover bolts a few turns in progression until all are tight. Guide the transmission into place, using care to see that the driven disc is not bent. Use a floor jack to support the transmission so that the clutch shaft may be guided through the driven disc safely.

Fig. 5 Lipe-Rollway clutch adjustments

Fig. 7 Rockford Type TT clutch

ALLISON REOMATIC

Range Selector Linkage

1. Move range selector lever from L to R. Six definite detent positions should be felt as the lever moves from front to rear. If not, adjust as follows:
2. Place selector lever at R.
3. At transmission, disconnect range selector cable from transmission control lever.
4. Push control lever (inner lever on transmission) all the way forward and upward.
5. Push control cable up until the selector lever hits the R stop. Adjust threaded clevis so that clevis pin just fits hole in control lever.
6. Assemble clevis to control lever.
7. From driver's seat, again feel for full engagement at each detent position before the lever hits its stop.

Hydraulic Retarder Linkage

The retarder valve, located on the right side of the transmission, must travel a full ½" toward the rear just before the retarder pedal hits the stop bolt. When pedal is released, the valve must travel ½" to cross shaft to insure full return of pedal. If necessary, adjust as follows:

1. Disconnect hydraulic control rod at transmission end. Pull retarder lever toward rear until the valve is heard and felt to bottom in the retarder valve body. Pull control rod down until pedal contacts its stop bolt.
2. With retarder valve bottomed and pedal against its stop, adjust control rod clevis until the clevis pin just fits into the lever hole.
3. Lengthen control rod by backing off adjusting clevis until there is ⅛" clearance between pedal and its stop bolt at full retarder application.
4. Assemble control rod to lever and recheck adjustment by depressing pedal against the stop bolt. Just before it hits the stop, the retarder valve should be felt to bottom in its body.
5. Check for full release and readjust if necessary.

Throttle Linkage

1. Check engine idle adjustment (475-500 rpm).
2. Disconnect throttle control rod from transmission TV (outer) lever.
3. Depress accelerator pedal down "to detent" (not "through detent"). The carburetor lever should now be against its full throttle stop.
4. Push transmission TV lever forward and upward until it is against its stop inside transmisson. With TV lever firmly against the stop, and the accelerator pedal "at detent", adjust throttle control rod clevis so that pin just fits through holes.
5. Remove pin and lengthen control rod by turning clevis out 7 turns counterclockwise.
6. Assemble clevis to control lever.
7. Adjust accelerator stop bolt so that there is a clearance of $\frac{1}{16}$" between pedal and bolt head when throttle linkage hits its stop "through the detent". This will provide full travel in the linkage without undue deflection.

Road Test

After making the throttle linkage adjustment outlined above, road test the truck to check the operation of the transmission.

1. If the 3-4 full throttle ("at detent") shift occurs at an engine speed considerably under governed speed, it is probable that the throttle linkage is not properly adjusted. Shorten the throttle control rod at the transmission lever one full turn at a time and repeat the test until the shift occurs at 3100-3300 rpm engine speed.
2. If full throttle 3-4 shift did not occur, and the engine reached governed speed, it is probable that the throttle linkage is too short and should be lengthened one full turn at a time until the shifts occur at 3100-3300 rpm engine speed.
3. Governed speed with the OH-170 engine should be 3400 rpm full load and 3550-3650 rpm no load.

Steering Gear Section

ROSS CAM & LEVER

These gears, Figs. 1, 2 and 3, are the cam and lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove causing the lever arm to rotate the lever shaft. As an aid to easy steering the lever shaft studs which engage the cam are mounted on tapered roller bearings. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and the cam where most of the steering action occurs.

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the lock nut and adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are .002", .003" and .010" thickness.
4. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim. If necessary, remove or replace shims until the adjustment is correct.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then starting from this point count the number of turns required to reach end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but a slight drag should be felt in the mid-position only.
3. After proper adjustment is secured, tighten lock nut and give the gear a final check for binding.

Stud Roller Bearing, Adjust

In most cases the foregoing adjustments will be adequate but it is sometimes necessary to adjust the stud roller bearing units as they should be preloaded at all times. A heavy drag should be felt when revolving the studs by hand. If a torque wrench is available the bearings should be adjusted so that the torque required to revolve the stud is as follows:

Lever Shaft Dia.	Torque, In. lb.
1⅜"	3-4
1½"	3-4
1⅝"	4-8
1¾"	5-11

1. To adjust, remove lever shaft from housing, wash the bearings in solvent and blow dry with compressed air, using care not to spin the bearings. Lubricate the bearings with light oil.
2. Straighten out the prong of the locking washer to release the stud nut. Remove the nut and install a new locking washer.
3. While holding the stud nut from turning with a spanner wrench on the locking washer, tighten the nut as required to revolve the stud in accordance with the table above.
4. When proper adjustment has been secured, bend the prong of the washer against a side of the nut to keep it from turning.
5. Lubricate the bearings with gear oil and assemble the lever shaft in the steering gear housing.

Fig. 1 Ross cam and lever steering gear with twin studs

Fig. 2 Ross cam and lever steering gear with single roller bearing mounted stud

GEMMER WORM & ROLLER GEAR

Means for mechanically eliminating all play within the mechanism have been provided. There is no need of being forced to choose between a stiffly operating unit and one having lost motion, since all of the adjustments can be set at the will of the adjuster at the most desirable point, with external adjustments.

In this type of gear, Fig. 4, the worm adjustment is accomplished with the use of shims. The need for adjustment, however, should present itself only after considerable usage.

Before altering any adjustments, jack up front wheels of car and make sure that cause of complaint is not from some other looseness such as ball sockets, and so forth. Then make the following test.

Inspection for Proper Worm Bearing Adjustment

Turn hand wheel about one turn to right from straight ahead driving position. Secure in this position to prevent any oscillation when front wheels are shaken violently. This can be done by tying one spoke to a left side door column and holding the wheel against it as a brace. Grip column with other hand just below hand wheel hub with side of finger barely touching lower end of hand wheel hub. Now have helper shake front wheels hard sidewise. This will enable any end play in worm bearings

Fig. 4 Gemmer worm and roller steering gear

Fig. 3 Ross cam and lever steering gear with twin roller bearing mounted studs

to be felt at wheel hub. If any end play exists, worm bearings need adjusting. Be sure end play is felt, and not be confused with play or give in jacket bushing. Worm bearing adjustment should be correct before further inspection of gear is made.

Worm Bearing Adjustment

Loosen four worm cover screws 1/8 inch, Fig. 4. Use a knife to separate the top shim, passing blade all the way around between shims, care being taken not to mutilate the remaining shims. Remove only one shim at a time between inspections, to remove end play. Care should be taken not to set up stiffness in worm bearings.

It is important the drag link be removed from steering gear ball arm in order to effect a satisfactory inspection of other adjustments and alignment of gear in vehicle. Now revolve hand wheel to determine if any stiffness exists. If so, too many shims have been removed or gear is misaligned in vehicle.

Correction of Gear Misalignment

Loosen the frame bracket bolts just enough to allow gear to shift in frame to line up at angle determined by height setting of instrument board gear bracket and retighten frame bracket bolts. Now loosen instrument board gear bracket and allow it to shift to match gear column position, and retighten. This will correct any possible misalignment of gear column.

Inspection for Proper Mesh of Shaft Roller in Worm

Never make inspection for proper mesh, without first correcting column adjustment and gear alignment. Turn hand wheel to the mid-position of its complete travel or turning limits. (Drag link previously disconnected.) Most hand wheels have a trade mark or large depression on the underneath side of the spoke that should now point straight upward, or straight down, whichever location is nearest to the mid-position. Place this marked spoke in correct position and shake ball arm to determine amount of lost motion. If this lost motion exceeds 1/32" at end of ball arm, roller shaft adjustment should be made.

Before drag link is again connected to steering gear ball arm, swing front wheels throughout their turning radius to determine if any tight spots exist. There should not be more than 10 lbs. pull on drag link either fore or aft throughout entire turning radius.

Use puller only to remove ball arm. Any other means will damage adjustment parts.

Roller Shaft Mesh in Worm Series 335-375

Adjustment for closer mesh of the shaft roller with the worm or, in other words, elimination of excessive play at this point, is accomplished by outside roller shaft adjustment screw. The position of roller contact with worm is offset from the center line of worm, hence when screw is tightened the roller is moved into closed mesh with the worm.

To adjust, remove roller shaft adjustment screw lock nut, slide off lock plate far enough to clear lock boss on roller shaft cover. Now be sure hand wheel is located in mid-position of wheel turns or straight ahead driving position and drag link previously disconnected. Tighten roller shaft adjustment screw just enough to remove play between roller shaft roller tooth and worm. Check this by amount of play felt at end of ball arm. It is better to leave a slight amount of play at this point than to tighten too much.

When tightened beyond the point of taking up lash, serious results will occur that are a detriment to continued good steering gear results.

Now slide lock plate in position against roller shaft cover and in locked position. Replace roller shaft adjustment screw lock nut and tighten.

Roller Shaft Mesh in Worm Series 400-500

Adjustment for closer mesh of the shaft roller with worm or in other words, elimination of excessive play at this point, is accomplished from the outside. The position of roller contact with worm is offset from the center line of worm, hence when roller is moved closer to worm center line, play is eliminated.

To adjust, be sure hand wheel is located in mid-position of wheel turns or straight ahead driving position and drag link previously disconnected. Now remove roller shaft adjustment lock nut plate and nut, slip off U shaped shaft thrust washer and one shim, (note there are two thickness of shims to permit close adjustment). Select the proper amount of shims to take out all play in this position without increasing the pull at hand wheel rim more than one pound over what it was when there was play between worm and roller in this center position. It is better to leave a slight amount of play between roller and worm than to remove too much shim and setup a tight adjustment.

Lock nut must be tightened securely to prevent rotation of shims and thrust washer. (Note there are four different locking positions obtainable by reversing adjusting nut lock plate.) Select position that will leave Adjustment Nut tightened securely and replace lock washer and stud nut.

①—When 259″ heavy duty engine is used in these models the engine will be identified by a 5E engine number. Heavy duty engines are further identified by the stenciled clover leaf symbol on the engine number boss.

②—When 259″ heavy duty engine is used in these models the engine will be identified by a 5E engine number. When 289″ standard duty engine is used the engine will be identified by a 7E number. When 289″ heavy duty engine is used engine will be identified by a 6E engine number. Heavy duty engines will be further identified by the stenciled clover leaf symbol on the engine number boss.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

Engine Section

CYLINDER HEAD

V8 Engines

1. If the right bank head is to be removed, remove generator and oil level gauge. Disconnect oil pressure gauge line.
2. If left bank head is to be removed, remove water temperature indicator and place it back out of the way. Disconnect oil filter inlet pipe and the fuel pump oil line from the head. Remove the battery.
3. Remove carburetor air cleaner.
4. Disconnect throttle control lever-to-cross shaft rod.
5. Disconnect fuel pump-to-carburetor fuel line at fuel pump.
6. Disconnect vacuum line at distributor.
7. Disconnect automatic choke tube at carburetor.
8. If left bank head is to be removed, remove choke tube.
9. Unfasten intake manifold and lift it off with carburetor.
10. Remove rocker arm assembly as outlined further on.
11. Loosen the U-clamp at the joint between the cross-over pipe and exhaust connection, and the U-clamp at the clutch housing. Remove studs from both manifold flanges, which allows the cross-over pipe and exhaust connection to drop off the manifold studs.
12. Remove two screws at water pump flange at front of head.
13. Loosen water pump screws.
14. Lift out push rods.

End view of V8 engine

Fig. 1 Cylinder head tightening sequence. V8 engines

15. Remove cylinder head screws and lift the head with its exhaust manifold off the hollow dowels. Be sure manifold heater valve is not damaged when removing right bank head.

Installation Notes

Since the right and left bank cylinder heads are identical, water pump ports are provided at the front and rear of all heads. It is necessary to block off the rear port, the one not in use, with a dummy plate and gasket. When installing a new head, check the capscrews holding the plate to the head to be sure they are right. The heat indicator cylinder head unit is mounted in the left head dummy plate.

Clean the face of the cylinder block and head. File or hone all high spots. If the cylinder head is warped, etched or brinnelled in excess of .015 in., it should be replaced. If warpage or brinnelling is less than .015 in., it is permissible to plane it off up to .015 in. to correct the condition.

Make sure the cylinder head oil return passage through the hollow dowel is clear. The dowels are also used to align the head and gasket during installation.

Apply gasket seal to the head gasket and install the gasket. Be sure the main oil gallery-to-rocker arm oil passage at the rear of the right bank or front of the left bank is clear and not blocked by the gasket.

To avoid losing torque to overcome friction between threads, dip capscrews in engine oil before starting them in the cylinder block threads.

Install nine short screws in the two outer rows of holes in the head and the five medium length screws in the center row and tighten them finger tight. Install the rocker arm assembly with the long screws and tighten them finger tight. Insert and tighten the rocker arm studs, tightening them alternately so that the assembly is pulled down evenly. Then tighten the cylinder head capscrews in the order shown in Fig. 1, and to the torque given in the *Engine Tightening* table.

After completing the balance of the installation, recheck the torque of the cylinder head or heads.

If a new rocker arm or rocker arm adjusting screw has been installed, make sure the adjusting screw is in far enough not to hold the valve open when normally it should be closed.

Engine lubrication diagram. Studebaker V8 engines

1961-63 overhead valve six cylinder engine

Start the engine and warm it up to approximately 160 degrees and torque the head in proper sequence to assure a tight and even seal of the gasket to the head and block.

Check the valve clearance and adjust if necessary. Adjust the throttle stop screw for proper idling.

1961-63 Six

1. Drain cooling system and remove upper radiator hose.
2. Remove rocker arm cover.
3. Remove spark plugs.
4. Remove manifold and carburetor as a unit.
5. Remove rocker arm shaft assembly.
6. Remove push rods.
7. Unfasten and remove head.
8. Reverse removal procedure to install head and tighten head bolts in the sequence shown in Fig. 2 to the torque listed in the *Engine Tightening Chart*.

L-Head Engines

The general procedure for removing the cylinder head is as follows:

1. Drain radiator.
2. Remove fuel line from carburetor to fuel pump.
3. Remove carburetor air cleaner.
4. Detach accelerator and choke controls at carburetor.
5. Remove carburetor.
6. If valve work is to be done, disconnect exhaust pipe from manifold and remove manifolds from engine.
7. Remove upper radiator hose, spark plugs, temperature gauge engine unit and cylinder head capscrews.
8. Lift cylinder head from block, using lifting hooks in two of the spark plug holes. Do not use a screwdriver, chisel or other sharp instrument to drive between the head and block to loosen the head as damage may result.

Installation Notes

Before the cylinder head is installed, make certain that all dirt and carbon is removed from both the head and block. File or hone all high spots.

If the cylinder head is warped, etched or brinnelled in excess of .015 in., it should be replaced. If warpage or brinnelling is less than .015 in., it is permissible to plane it off up to .015 in. to correct the condition.

Use a torque wrench when tightening cylinder head capscrews. Uneven or excessive tightening of nuts may distort cylinder bores, causing compression loss and excessive oil consumption.

Tighten cylinder head in the order shown in Figs. 3 and 4, tightening them a little at a time in the proper sequence a couple of times around before final tightening to the torque given in the *Tune Up* table. After the engine has warmed up to approximately 160 degrees, recheck the torque and tighten as required.

ROCKER ARM SERVICE

1961-63 Six

1. Before disassembly, mark the rocker arms, brackets and shaft so they can be reassembled in the original positions.
2. Hold rocker arm assembly and press on one end of the shaft end brackets and remove cylinder head capscrew from end bracket.
3. Gradually release compression of spring and carefully remove bracket, spacer, first rocker arm, compression spring and the next rocker arm from shaft.
4. Proceed in same manner to strip shaft of remaining parts.
5. Except when new parts are used, install all rocker arms and brackets on shaft in original positions. The two end brackets differ from the

Fig. 2 Cylinder head tightening sequence. 1961-63 overhead valve six

Fig. 3 Head tightening chart on Side valve 6-170 and 6-185 engines

Fig. 4 Head tightening chart on 6-246 engines

End view of 170 and 186 cu. in. six-cylinder engines

center brackets. *To insure correct installation and oil distribution, a flat is located on the front end of the rocker arm shaft.* Make certain that the oil holes and grooves in the shaft and oil holes in rocker arms and adjusting screws are clean. Clearance between rocker arms and shaft should be .0005″ to .0025″. If clearance is excessive, install new parts. Lubricate all parts with engine oil during reassembly.

V8 Engines

To remove the rocker arm assembly, proceed as follows:

1. Remove carburetor air cleaner.
2. Disconnect wires from spark plugs.
3. Drain cooling system.
4. Remove crown nuts from rocker arm cover and swing spark plug wires back out of the way.
5. Lift off rocker arm cover.
6. Remove four rocker arm bracket screws.
7. Unscrew four cylinder head capscrews that hold rocker arm assembly to head.
8. Lift off rocker arm assembly with cylinder head capscrews remaining in rocker arm shaft brackets.

Disassembly, Fig. 5

Before disassembly, mark rocker arms, brackets and shaft so that they can be reassembled in their original positions.

1. Push outer flat washer at one end of assembly so that the spring washer is compressed and remove cotter pin from shaft.
2. Remove washers and slip the end rocker arm off the shaft.
3. Holding the next rocker arm so that the spacer spring is compressed, remove cylinder head capscrew from end rocker arm shaft bracket. Still holding the spacer spring compressed, slide the bracket off the shaft.
4. Gradually release compression off the spring and remove the next rocker arm and spacer spring.
5. Proceed in the same manner to remove the remaining rocker arms, capscrews, brackets and springs.
6. Take the cotter pin out of the other end of the rocker arm shaft and remove the remaining washers.

Reassembly

Reverse the order of the above procedure to reassemble but before doing so check the following:

Under test the rocker arm spacer springs should require from 9½ to 10½ lbs. to compress each spring $2\frac{1}{32}$ in. A spring that does not test within these limits should be replaced.

Make certain that the oil holes and grooves in the rocker arm shaft are clean.

Clearance between shaft and rocker

Side view of 170 and 186 cu. in. six-cylinder engines

arms should be .0005 to .0025 in. Lubricate all parts with engine oil during assembly.

It is essential that the bottom of the rocker arm be on the oil groove side of the shaft and that the adjusting screw end of the rocker arm be on the same side as the cylinder head capscrew groove in the shaft, otherwise proper lubrication will not be achieved.

If correctly assembled, when installed on the engine, the flat on the end of the rocker arm shaft will be at the rear on the right bank and at the front on the left bank.

Installation

Place the rocker arm assembly on the head with the four cylinder head capscrews inserted through the head. Screw the capscrews down finger tight. Install the four rocker arm bracket screws and lockwashers. Tighten these screws alternately to avoid distortion of the assembly.

Make sure the push rods remain seated in the heads of the rocker arm adjusting screws and in the lifters.

Tighten the two inner cylinder head capscrews to 46-50 lbs. ft. torque and then the two outer capscrews to the same torque.

Before installing the rocker arm cover check the valve clearance and, if necessary, adjust as outlined further on.

Apply gasket seal to the flange of the rocker arm cover and place a new gasket on the flange. Install the rocker arm cover and complete the installation.

End view of 226 and 246 cu. in. six-cylinder engines

VALVES, ADJUST

1961-63 Six and All V8's

The drilled and grooved adjusting screw is self-locking. A torque of at least 30 lbs. in. should be required to turn the screw when the threads are engaged on both sides of the groove. If the torque is below the limit, valve clearance will not be maintained and the parts should be replaced.

The clearance for both intake and exhaust valves should be set to .014-.016 in. If the cylinder head capscrews are to be tightened, always complete the tightening process before adjusting valve clearances.

Fig. 5 Rocker arm assembly. V8 engines

To set the clearance the engine should be running at idle speed and the engine temperature should be stabilized at normal operating temperature.

After the choke tube and rocker arm covers have been removed, place the spark plug wire retaining brackets on the rocker arm assembly screws and secure them with the crown nuts. Then, with the engine idling, adjust the valve clearance by turning the adjusting screw as required to obtain the proper clearance as measured with a feeler gauge, Fig. 6.

L-Head Engines

Valves in these engines should be adjusted while the engine is at normal room temperature. The procedure is as follows:

Crank the engine over until the valve to be adjusted is fully closed. Hold the tappet body with a tappet wrench to prevent it from turning. Then turn the adjusting screw until the proper clearance is obtained (see *Tune Up & Valve Specifications* table). Adjust remaining tappets in the same manner.

On Champion engines the tappet ad-

Side view of 246 cu. in. six-cylinder engines

Fig. 7 Self-locking tappet adjusting screw

justing screw, Fig. 7, is self-locking. When one of these screws is replaced the torque required to turn the screw should be measured with a spring scale as shown in Fig. 8, and should register at least 25 lbs. in. If it doesn't, replace the screw.

VALVES, REMOVE

1961-63 Six and All V8's

After the cylinder head has been removed as outlined previously, remove the spark plugs to avoid damage to them. It is not necessary to remove the exhaust manifold.

Place a suitable holding strap over the valve heads to hold the valves in place while compressing the springs. Cylinder Head Holder Tool No. J-4674, Fig. 9, is available for valve work on these engines.

In using the tool as shown, do not compress the valve springs any more than is required to remove the locks and seals, Fig. 10. If they are compressed until the coils bottom, the springs will lose as much as 10 to 15 pounds tension.

After removing all locks, seals, springs and dampers, invert the head, remove the valve holding strap and lift out the valves. Place the valve in a board with numbered holes so that they can be identified as to the valve port from which they were removed.

Installation Notes

The spring dampers should be inspected to be sure that the fingers are not bent out. The fingers must contact the sides of the springs. Install the

Fig. 8 Using spring scale to check tension on self-locking tappet adjusting screw

Fig. 6 Adjusting valves. V8 Engines

Fig. 9 Removing valve keepers with aid of special cylinder head holding fixture. V8 Engines

Fig. 10 Layout of valves and related parts. V8 Engines

Fig. 11 Showing special tool used to control position of valve guides when driven in place. V8 Engines

dampers so they are on the closed coil end of the springs.

Install the valve spring retainers on the springs, making sure the retainers with the skirts are on the intake valves, Fig. 10. Compress the spring until the retainer is past the inner groove of the valve stem far enough to permit installing the rubber seal.

The seal must not be installed before the retainer is installed because pressing the retainer over the seal would damage the seal. Always install new rubber seals.

L-Head Engines

To remove valves from these engines, take off the cylinder head and valve covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so they can be identified as to the valve port from which they were removed.

VALVES, GRIND

All Engines

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum amount of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}$", otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the block or head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing has a valve guide pilot.

The valve seat width after refacing should be $\frac{5}{64}$" to $\frac{7}{64}$" on the intake. The width of exhaust seats should be $\frac{7}{64}$".

A simple check can be made to prove the fit of the valve in the valve seat by spreading a thin film of Prussian Blue on the valve face and inserting the valve in the valve seat. With hand pressure, rotate the valve ¼ turn, remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer will indicate an inaccurate valve and valve seat operation.

VALVE SPRINGS

All Engines

Wash the springs with gasoline or other suitable solvent. Then examine them for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring pressure on a spring testing fixture, if one is available. If a fixture is not available, at least check the free length of each spring by standing it alongside a new one. Any spring that does not conform to the specifications in the *Valve Specifications* table within 10 per cent should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded.

VALVE GUIDES, REPLACE

1961-63 Six and All V8's

Clean the valve guides with a wire guide brush, and clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads, as well as the gum which might have accumulated on the stems.

Check the valve stem-to-guide clearance with a dial indicator if one is available. Mount the indicator on the valve guide so that the button contacts the valve stem squarely and as near the end of the guide as possible. Then move the valve stem away from the indicator. Note the total clearance reading. If the guides are worn so that the reading exceeds .0035 in., new guides should be installed.

Fig. 12 For correct valve timing, gears must be installed so the timing marks mesh as shown. V8 Engines

Fig. 13 Timing gear installation. All Sixes

The special Valve Guide Tool shown in Fig. 11 should be used to remove and install guides in these engines. When removing a valve guide, use the driver to drive the guide out of the cylinder head from the combustion chamber side.

When installing a guide, first coat the outside of the guide lightly with white lead. Then start the chamfered end of the guide into the head from the combustion chamber side. Place the installing plate on the face of the head as shown in Fig. 11 and drive in the guide until the shoulder of the driver contacts the bottom of the counterbore in the plate. The plate is marked "Intake" on one side and "Exhaust" on the other. Be sure the exposed mark of the plate corresponds to the valve guide being installed.

If the special tool is not available, carefully measure the position of the guides before removing them and drive the new ones in accordingly.

L-Head Engines

To check valve stem-to-guide clearance, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance (over .0035 in.) it will be necessary to replace the guide. If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

If it is necessary to replace valve guides, the old guides can be driven down and out of the valve chamber. A special driver is available for this work. However, in lieu of the driver, the guides can be pulled out of the block by using a suitable piece of pipe together with a long bolt and suitable washer.

Be sure the new guides are driven to the correct position in the block. This can be determined by measuring the position of the old guides before they are removed.

Fig. 14 Camshaft end thrust control on all engines

VALVE LIFTERS

1961-63 Six and All V8's

A straight barrel type lifter is used. To remove the lifters, take off the cylinder heads and push rods as outlined previously. Then remove the three capscrews that retain the valve lifter chamber cover and breather pipe and lift off the cover and pipe.

Take out the valve lifters, keeping them in order so they can be replaced in the same bore from which they were removed.

Wash the lifters with clean gasoline or other solvent. Remove the carbon and sludge deposits from the oil holes. Inspect all lifters for excessive wear and replace where necessary.

L-Head Engines

Mushroom type lifters are used on all six cylinder engines which means that the oil pan and camshaft must be removed and the lifters taken out from below when lifters require replacement.

TIMING GEARS

All Engines

For correct valve timing, timing gears should be assembled as shown in Figs. 12 and 13. Always use suitable puller and pusher equipment when servicing gears. This is particularly important in the case of the camshaft gear as there is danger of loosening the welch plug in back of the camshaft if the gear is driven on with hammer blows.

Camshaft gears are available in two sizes and are marked "S" for standard and "H" for high limit. The crankshaft gear is furnished in the standard size only. Whenever new gears are installed they should be selected to give .001 to .003 in. backlash.

CAMSHAFT

V8 Engines

To remove the camshaft from these engines, proceed as follows:

1. Turn the crankshaft until the timing marks show the "IGN" mark directly under the pointer on the timing gear cover and the distributor rotor is in position to fire No. 6 cylinder. In this position the timing mark on the camshaft gear is properly aligned between the marks on crankshaft gear, Fig. 12.
2. Remove rocker arm assembly, push rods and valve lifters.
3. Remove distributor drive shaft assembly.
4. If the oil pump is not to be removed, the relationship between the positions of the crankshaft and the oil pump shaft must be maintained after the removal of the distributor drive shaft. Therefore, to avoid difficulty in meshing the tongue of the distributor drive shaft with the groove of the oil pump shaft do not turn the crankshaft after it is once positioned with the timing mark under the pointer.
5. Remove water pump, vibration damper, pulley and hub, and take off the timing gear cover.
6. Remove the two screws which fasten the camshaft thrust plate to the cylinder block and withdraw the camshaft and gear as a unit, being careful not to damage the camshaft bearings.

6-Cylinder Engines

To remove the camshaft, take off the radiator and all necessary sheet metal Remove vibration damper and pulley. Remove the timing gear cover and screws which fasten the camshaft thrust plate to the cylinder block. Take off the manifolds, cylinder head, fuel pump, oil pump and valve covers.

If removal of the valves is not intended, raise the lifters and keep them up with spring-type clothespins or metal supports so they won't interfere with the camshaft as it is being withdrawn.

Fig. 15 Piston and rods. V8 Engines

Fig. 16 Detail of piston pin lock screw. All Sixes

Camshaft End Play

Camshaft end play is controlled by a thrust plate, Fig. 14, located between the front camshaft bearing and camshaft gear.

On 6-cylinder engines, end play of .004 to .008 in. is permissible and is regulated by the amount by which the thickness of the thrust spacer exceeds that of the thrust plate. However, if a new thrust plate and spacer are installed, the end play should be held to .004 to .006 in. Use a micrometer to measure both parts.

On V8 engines, end play should be from .005 to .007 in. and is regulated in the same manner as for the L-head engines.

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out through the top of the cylinders, using care to prevent the big end of the rods from damaging the crankshaft or cylinders.

Make sure the rods and pistons are properly numbered so they can be reinstalled in the original locations. It is advisable to install caps on rods to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

V8 Engines

Pistons should be assembled to the con-

necting rods so that the oil squirt holes are on the same side as the unslotted side of pistons. And when installed in the cylinders the T-slot side of all pistons should be toward the left side of the engine, Fig. 15. In other words, the T-slot side of left bank pistons should face away from the camshaft whereas the T-slot side of right bank pistons should face the camshaft.

6-Cylinder Engines

When correctly assembled the oil squirt hole in the connecting rod will be on the camshaft side of the engine with the T-slot side of the piston facing away from the camshaft.

PISTONS, REPLACE

Standard size service pistons are high limit or maximum diameter; therefore, they can usually be used with a slight amount of honing to correct slight scoring or excessive clearances in engines having relatively low mileages. Service pistons are also furnished in .005, .010, .015, .020 and .030 in. oversizes.

Before a honing or boring operation is started, measure all new pistons with a micrometer at points exactly 90 degrees away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is very important that refinished cylinder bores are trued up to have not more than .0005 in. out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at the same temperature (room temperature of 70 degrees) when the piston is checked for fit in the cylinder bore. Therefore, the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10 degrees between the temperature of parts is sufficient to produce a variation of .0005 in.

Fig. 17 Checking bearing clearance with Plastigage. All engines

Fig. 18 Crankshaft end play control on all engines

PISTON RINGS, REPLACE

When new piston rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the bore's diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap or rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with either end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

PISTON PINS, REPLACE

Service piston pins are available in standard and .0025 and .005 in. oversizes. When fitted correctly in the piston, pins should require a light finger push with parts at room temperature of approximately 70 degrees.

V8 Engines

To remove the piston pin, remove the lock nut and star washer from the clamp screw, Fig. 16. Install and tighten the lock nut on the other end of the clamp screw, which will loosen the clamp screw in the rod. Remove the screw from the rod and slide the piston and rod off the pin.

To install the pin, slide the piston and rod into position. But before inserting the clamp screw, be sure the solid side of the piston is to the squirt hole side of the rod.

If the connecting rod is a new one and hasn't been marked, it should be checked to determine whether it is a left or right bank rod. The rods are offset at the crankpin end and can be identified as shown in Fig. 15.

Install the piston pin clamp screw so that the nut will be installed on the T-slot side of all pistons. Be sure the flat surface of the clamp screw mates with the flat surface of the piston pin, otherwise the pin will work loose in service.

6-Cylinder Engines

On these engines the piston pin is locked in the rod in the same manner as for V8 engines, Fig. 16. However, on connecting rods 1, 3 and 5, the clamp screw nut is installed on the T-slot side of the piston. On Nos. 2, 4 and 6, the nut is installed on the solid side of the piston.

When installing the clamp screw regardless of the rod number, hold the rod with its offset to the left and insert the screw from the front. This will locate the lock nut on the correct side with relation to the piston.

ROD BEARINGS, REPLACE

Connecting rod bearings in these models consist of two half shells, the upper shell having an oil hole which communicates with an oil hole in the rod.

When the shells are placed in the rod and cap the ends extend slightly beyond the parting faces so that when the rod bolts are tightened the shells will be clamped tightly in place to insure positive seating and to prevent turning. *The ends of the shells must never be filed flush with the parting surface of the rod and cap.*

If this type bearing becomes noisy or is worn so that the clearance on the crankpin is excessive, a new bearing of proper size must be selected and installed since no provision is made for adjust-

Fig. 19 Installing neoprene seals in bearing cap grooves. All engines

Fig. 20 Installing Brummer oil seal

ment. Under no circumstances should the rod or cap be filed to adjust bearing clearance.

Service bearings are furnished in standard size and several undersizes, including undersizes for reground crankshafts.

The clearance for connecting rod (and main) bearings may be checked with Plastigage which is available at any auto parts jobber and full instructions for its use are furnished with the envelope in which it is contained, Fig. 17.

Lacking Plastigage, however, clearance may be checked with a .002 in. test shim, ¾ in. square. Place the shim between the bearing and shaft journal. Install the bearing cap and tighten the nuts to the recommended torque of 28-32 lbs. ft. on Champion engines and 50-55 lbs. ft. on Commander engines. A locked bearing or drag when the rod is moved endwise on the crankshaft indicates the clearance is correct providing the rod moves endwise freely without the test shim installed. Do not overlook removing the test shim.

Connecting rod nuts are locked with stamped nuts which should not be reused when once removed. Install these nuts with the flat face toward the connecting rod nut. Turn the locking nut finger tight and then tighten it an additional one-third turn with a wrench.

MAIN BEARINGS, REPLACE

Main bearings are the shell type and can be removed and replaced without removing the crankshaft. The bearings are made to size and do not require line reaming or adjustment.

When it is necessary to install new bearing shells, it is advisable to measure the shaft journals with a micrometer for being out-of-round. If an out-of-round condition exists in excess of the standard running clearance of the bearings (either main or connecting rod) a satisfactory bearing replacement cannot be made and it will be necessary to replace or regrind the crankshaft.

Use a rifle brush to clean the oil passages in both the shaft and crankcase. If possible, blow out the oil holes with compressed air. Be sure the journals are not nicked or scored and that all parts are thoroughly clean.

After installing the bearings, check the running clearance to be sure it is standard (see *Engine Bearing Data* chart). Use Plastigage or a .002 in. test shim about one inch square. Place the shim between the shaft and bearing and tighten the bearing cap nuts to the recommended torque of 88-93 lbs. ft. The shaft should be locked if the clearance is at the low limit or show a drag if at the high limit when turned, proving that the clearance is correct. Do not overlook removing the test shim.

CRANKSHAFT END PLAY, ADJUST

Crankshaft end play is controlled by shims located between the vertical surface of the front main bearing journal and the crankshaft thrust washer, Fig. 18.

Whenever new bearings are fitted the clearance should be carefully checked and shims should be added or removed as required to bring the end play within the limits given in the *Engine Bearing Data* chart.

End play can be measured by forcing the crankshaft forward and inserting feeler gauges between the crankshaft gear and thrust washer.

CRANKSHAFT OIL SEAL, REPLACE

Oil sealing at the rear main bearing is controlled by a Brummer oil seal installed around the crankshaft journal, wood filler blocks between the sides of the main bearing cap and block, and Neoprene seals between the bearing cap face and block.

1. Remove crankshaft rear bearing cap and all the old oil seals.
2. Wash bearing, blow dry and wipe clean.
3. Loosen the intermediate bearing caps approximately two turns to give additional clearance between the rear journal and block.
4. Insert the Neoprene seals in the cross grooves of the rear bearing cap so that the inner end of each seal is inset $\frac{11}{64}$ in., Fig. 19.
5. Press the seals uniformly and firmly into the grooves.
6. Place the cap with the seals downward on a flat surface and, while pressing on the cap, use a sharp knife or razor blade to cut the protruding ends of the seals flush with the side of the cap.
7. If the engine was not originally equipped with this type seal, use the flat side of a screwdriver to blunt the sharp edge of the flange, Fig. 20, on which the seal is to be mounted. It is not necessary to remove any material from this edge but only to blunt it so that it does not scuff the soft center sealing cushion at the bottom of the groove since this cushion is as important a part of the seal as the compression flange which wipes the crankshaft.
8. Before installing the Brummer oil seal, clean the channel just forward of the crankcase rear flange by pulling a swab saturated with alcohol or a similar solvent through the channel several times. Then dry the channel thoroughly.
9. Dip the ends of the seal in liquid soap and spread the soap throughout the inside of the outer groove.
10. Spread the seal just enough to permit aligning one end of it with the crankcase rear flange and insert the seal as shown in Fig. 20.
11. Carefully work the seal around the crankshaft until the end emerges on the opposite side, Fig. 21.
12. Now align the seal, reverse the direction of rotation and insert the other end of the seal.
13. Continue to turn the seal until the joint is approximately 45 degrees from the lower surface of the block.
14. Apply oil between the compression

Fig. 21 Installing Brummer oil seal

Fig. 22 Removing "C" washer to disassemble oil pump. 170 and 186 cu. in. engines

Fig. 23 Typical sealed ball bearing type water pump used on all L-head engines

Engine lubrication diagram. Overhead valve 6-cylinder

flange of the seal and the crankshaft journal.

15. Install the bearing cap and the two Neoprene seals.
16. Install bearing cap screws and tighten to specified torque. Tighten intermediate bearings caps.
17. Install the two wood filler blocks, being sure the blocks are not damaged or split during the installation.
18. Complete the job and run the engine for 45 minutes and check for oil leaks.

OIL PUMP REPAIRS

6-Cylinder Engines

Before removing the oil pump, crank the engine to bring No. 1 piston to its firing position, which is when the ignition mark on the vibration damper or flywheel is in line with the pointer. If possible, leave the engine in this position while the pump is off in order to obtain correct ignition timing. However, if the engine is disturbed while the pump is off, return it to the No. 1 firing position before attempting to install the pump.

On 170 and 186 cu. in. engines, removal of the oil pump is a piece-by-piece operation. Take off the bottom cover and pick out the "C" washer, Fig. 22, from the pump shaft. Remove the body and pull out the shaft and gears.

Reverse the operations to assemble, being sure the engine is in the position to fire No. 1 cylinder.

V8 Engines

Removing the pump from these engines does not effect the ignition timing. After removing the oil pan as previously outlined, remove the two pump retaining nuts and slip the pump from the mounting studs.

WATER PUMP REPAIRS

6-Cylinder Engines

These models use the seal type, ball bearing pump, Fig. 23.

To disassemble, remove the bearing lock ring and press the shaft and bearing out through the front of the housing. Pick out the seal parts, being careful to note their arrangement so that upon reassembly, leakage will be avoided.

Inspect the parts for damage or wear. If the thrust seal surface is rough, it should be refaced with a suitable facing tool. Always use a new impeller and seal assembly. And to insure a tight fit, use a new fan hub.

When assembling, press the fan hub on the shaft so that it is flush with the end of the shaft. Install the shaft and bearing and insert the bearing lock ring. Slip the seal parts into the impeller and press the impeller on the shaft, allowing 1/32 inch clearance between the impeller and housing.

V8 Engines

To remove the water pump, drain the cooling system and remove the fan belt, fan and pulley. Disconnect all water hose. Remove the generator adjusting arm from the top stud. Then remove the seven capscrews holding the pump housing to the engine. Lift off the water pump and four gaskets.

To disassemble the pump, remove the cover and impeller from the pump housing. Pull out the bearing lock ring. Place the assembly in an arbor press and press the hub, shaft and bearing assembly out of the impeller and cover. Then press the shaft and bearing out of the hub.

Inspect the parts for wear or damage. If the thrust seal surface in the housing has become rough, it should be refaced with a suitable facing cutter.

In assembling the pump, a new fan hub should be used to insure a tight fit on the shaft. Press the fan hub on the shaft so it is flush with the end of the shaft. The impeller should be pressed on the shaft so it too is flush with the end of the shaft.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if the fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading on carburetors with automatic choke may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a foreign matter. A magnet moved through choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Automatic Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

Fig. ②—WCFB float level.

Fig. ③—WCFB float drop.

CARTER NOTES

METERING ROD

WCFB—Metering rod adjustment must be made after completing pump adjustment. No gauges are necessary. Back out throttle lever set screw so throttle valves are fully seated and loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link unt'l metering rods bottom on casting. Holding rods down and throttle valves seated, revolve metering rod arm until finger on arm contacts lip of vacumeter link. Hold in place and tighten clamp screw.

AS—Metering rod should just bottom at wide open throttle. Adjust by bending metering rod arm.

CARTER NOTES Continued

Fig. ④—With pump connector link in outer hole of pump arm (long stroke) and with throttle valves seated, hold straight edge across top of dust cover boss at pump arm. Flat on pump arm should be parallel to straight edge. Adjust by bending throttle connector rod at lower angle.

⑤—Loosen choke lever clamp screw on choke shaft. Insert .020" feeler gauge between lip of fast idle cam and boss of flange casting. Hold choke valve closed and take slack out of linkage by pressing choke lever towards closed position; hold in place and tighten clamp screw. With choke valve tightly closed, tighten fast idle adjusting screw until there is the clearance listed between throttle valve and carburetor bore (side opposite idle port). Be sure fast idle adjusting screw is on high step of fast idle cam when making this adjustment.

⑥—With throttle wide open there should be the clearance listed between upper edge of choke valve and inner wall of air horn. Adjust by bending unloader lip on throttle shaft lever.

Fig. ⑦—AS float level. Adjust by bending float lip. After adjusting, there should be .010" to .015" clearance between overlapping tangs of float levers. Bend long tang on left hand float to adjust.

⑧—Pump arm on lifter link should parallel top of casting. Bend pump arm to adjust.

Fig. ⑨—There should be the clearance listed between lower edge of choke valve and carburetor bore with fast idle link on high step of cam. Adjust by bending choke connector rod.

Fig. ⑩—There should be the clearance listed between top edge of choke valve and inner wall of air horn. Adjust by bending arm on choke trip lever.

⑪—Measured at outer ends of float from casting with carburetor inverted with weight of float on needle.

⑫—Measured from air horn to top of float with air horn inverted.

⑬—Measured from pump plunger washer to boss on bowl with throttle valve fully closed and choke open.

⑭—Measured from bowl cover to top of pump plunger with throttle valve fully closed.

⑮—Measured between throttle valve and idle port side of carburetor bore while on fast idle step.

⑯—Measured at air horn inner wall to edge of choke valve with wide open throttle holding choke closed.

⑰—Between upper edge of choke valve and inner wall of air horn with wide open throttle and choke held closed.

STROMBERG NOTES

CARBURETOR BALL CHECKS

Whenever it becomes necessary to dismantle a carburetor be sure to account for the ball check valves that may be found under pump plungers and compensating or power valves.

Fig. ①—WW float level. To adjust bend lip of float lever.

②—Close choke so that high step of fast idle cam contacts fast idle screw. Turn fast idle screw until the clearance specified exists between throttle valve and carburetor bore on idle port side.

Fig. ③—Hold choke valve lightly closed. Then open throttle until throttle lever stop rests against throttle body stop. Choke should be open the dimension specified between narrow side of choke valve and inner wall of air horn. Adjust by bending throttle lever ear.

⑤—Measured between throttle valve and idle port side with cam on highest step.

Fig. ④—With choke valve fully closed and fast idle cam in fast idle position one-half the diameter of the button at the end of the throttle stop screw should rest against the step of the fast idle cam. Adjust by bending choke lever ear.

Clutch & Transmission Section

For New Process and Warner transmissions used on Studebaker trucks, see the "name" chapters for service procedures and lubricant capacities

BORG & BECK

These clutches are single plate, dry disc types with no internal provision for adjustment for wear. However, each release lever is adjusted individually to the correct height, and no attempt should be made to adjust these levers unless the clutch is to be dismantled for overhaul. Overhauling the clutch should not be attempted unless a clutch rebuilder is available. Lacking this equipment it is recommended that the clutch cover and pressure plate assembly be exchanged for a rebuilt unit.

Clutch Pedal, Adjust

The general procedure for adjusting the clutch pedal is to shift the pedal down away from the toe board until the clearance or free movement is ¾" to 1". The pedal pad should come in contact with the toe board when the pedal is pressed down. If it does not move that far, making it necessary to spring the pedal to make the pad touch the toe board, shift the pedal down a little more.

Press the pedal down and note the distance the release bearing travels after it comes in contact with the release levers. To obtain a clean release the levers should be pushed toward the flywheel $\frac{7}{16}$". If it does not travel this distance shift the pedal up, bearing in mind that the pedal pad must touch the toe board as above.

Clutch Assembly, Replace

After removing the transmission, but before removing the clutch, mark with a punch the flywheel, clutch cover and pressure plate so that these parts may be assembled in their same relative positions and in the same position on the flywheel if the same clutch is to be reinstalled. This is important because they are balanced as an assembly.

To remove the clutch, pull out the clutch release bearing and sleeve. Unfasten the clutch cover from the flywheel, loosening each cap screw a few turns in succession until the cover is free. The clutch assembly and driven disc can then be removed from the flywheel.

When installing the clutch, coat the pilot bearing in the end of the crankshaft with wheel bearing grease. Clean the surfaces of the flywheel and pressure plate, making certain no oil or grease remains on these parts. Hold the cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the pilot bearing in the crankshaft. Bolt the clutch cover loosely to the flywheel, being sure the punch marks previously made are lined up. To avoid distortion of the clutch cover, tighten the cover bolts a few turns each in progression until all are tight. Guide the transmission into place, using care to see that the driven disc is not bent. Use a floor jack to support the transmission so that the clutch shaft may be guided through the driven disc safely. Adjust the clutch pedal free travel.

INLAND CLUTCH

This type clutch is a single dry disc type with a diaphragm spring. The driven member is the cushion type with dampener springs at the hub. The cover and pressure plate assembly is bolted to the engine flywheel and the disc is gripped between the friction surfaces of the pressure plate and flywheel. The clutch disc is splined to the main drive gear which is part of the transmission.

Disassemble

1. Remove three drive strap-to-pressure plate bolts and retracting springs and remove pressure plate from clutch cover. *When disassembling, note position of "O" marks on pressure plate and cover. These marks must be aligned when assembled to maintain balance.*
2. The clutch diaphragm spring and two pivot rings are riveted to the clutch cover. Spring, ring and cover should be inspected for excessive wear or damage and if there is a defect, it is necessary to replace the complete cover assembly.

Inspection

1. Wash all parts except throwout bearing in cleaning solvent. *The throwout bearing is permanently packed with lubricant and should not be soaked in cleaning solvent as this may dissolve the lubricant.*
2. Inspect pressure plate and flywheel for scores on the contact surfaces.
3. Check drive straps for looseness at the clutch cover rivets and for evidence of looseness at the pressure plate bolt holes.
4. Check throwout bearing for roughness and for free fit on sleeve of transmission clutch gear bearing retainer.
5. Check run-out of transmission pilot hole in clutch housing by removing a flywheel bolt and installing a dial indicator. Run-out should not be more than .008"
6. Check fit of ball in clutch fork, which should be snug without end play.
7. Inspect clutch disc for worn, loose or oil soaked facings, broken springs, loose or riding rivets.
8. Examine splines in hub and make sure they slide freely on splines of transmission clutch shaft. If splines are worn, the clutch should be replaced.

Assemble

1. Install pressure plate in cover, lining up "O" mark [on pressure plate with "O" mark] on flange of cover.
2. Install pressure plate retracting springs and drive strap-to-pressure plate bolts and lockwashers and torque to 11 lb. ft. The clutch is now ready to be installed.

Rear Axle Section

For Eaton and Timken (Rockwell) driving axles used on Studebaker trucks, see the "name" chapters for service procedures and lubricant capacities

Fig. 1 Spicer single-reduction axle with one-piece banjo type housing

SPICER

One-Piece Housing Type

This rear axle, Fig. 1, is of the semi-floating, hotchkiss drive type. The drive pinion is the over-hung type, mounted on pre-loaded taper roller bearings. Sealing of the pinion shaft is accomplished at the front end by a spring-loaded leather seal bearing on the companion flange, which is splined and secured to the pinion shaft by a nut.

Axle Shaft, Remove

To remove an axle shaft, jack up the wheel and pull off the hub and brake drum. Block the brake pedal in such a manner that it cannot be depressed. Disconnect the hydraulic brake line from the wheel cylinder. Remove the mounting screws and take off the outer oil seal, shims and brake support. The shaft and bearing may then be pulled out of the housing. The inner oil seal may be removed at this time.

Axle Shaft, Install

Replace the shaft and bearings in the reverse order. If the old parts are replaced and the shims have not been disturbed, the end play should be correct when the parts are assembled. However, if a new axle shaft, bearing, differential carrier or housing has been installed, it will be necessary to check the end play.

Axle Shaft End Play, Adjust

Axle shaft end play can be checked when all parts have been replaced except the wheel and hub. To make the check, rap each axle shaft after the nuts are tight to be sure the bearing cups are seated. Then mount a dial indicator on the axle housing with its contact button touching the end of the shaft. Work the shaft in and out by hand and note the reading on the indicator. If an adjustment is necessary, remove the oil seal and brake support and add or remove shims as required to bring the end play to .001" to .005".

When making this adjustment, an equal thickness of shims should be removed or added on each side of the axle housing to maintain the central position of the axle shafts.

Fig. 2 Prying differential from housing. Spicer axle

Rear Axle Assembly, Replace

Inasmuch as the axle tubes are pressed into the differential carrier to form a one-piece housing, the rear axle assembly must be removed from the chassis when it becomes necessary to overhaul the unit.

1. Raise vehicle from floor and support with stand jacks under frame side rails.
2. Remove rear wheels.
3. Split rear universal joint.
4. Disconnect parking brake cable from operating lever and from brake backing plates.
5. Disconnect hydraulic brake line connection at rear axle housing.
6. Loosen and move shock absorbers out of the way.
7. While supporting axle housing with hydraulic jack, remove spring clips and lower axle assembly to the floor.
8. Reverse the foregoing procedure to install the rear axle assembly, being sure to bleed the brake system when the installation is completed.

Fig. 3 Adjustments on Spicer axle

Fig. 4 Checking clearance between bearing cup and differential case. Spicer axle

Differential Carrier, Disassemble

1. Remove axle shafts as outlined previously. Axle shafts may be pulled out only far enough to clear differential side gears.
2. Drain lubricant and remove rear cover.
3. Make sure differential side bearing caps and axle housing are marked, then remove the side bearing caps.
4. Pry differential from housing, Fig. 2.
5. Remove side bearing cups.
6. Pull off side bearings and adjusting shims, tagging the shims for identification on reassembly.
7. Unfasten ring gear from case.
8. Drive out differential pinion shaft pin and pull out the shaft, pinions and side gears.
9. Hold companion flange from turning and remove flange nut.
10. Pull flange from pinion shaft.
11. Remove pinion from carrier by tapping on front end with soft hammer.
12. Remove pinion shaft bearing oil seal and bearings from carrier, keeping separate the shim pack at each bearing.

Pinion & Bearings, Replace

If the original ring gear and pinion are being used in the original carrier, use the original shim packs at each bearing, Fig. 3. If a new pinion or differential carrier is installed, note the markings on the end of the pinion gear and on the differential carrier to obtain the correct thickness of shimming to be used with these parts from your supplier. The shims behind the rear bearing establishes the correct pinion depth.

1. Press the rear pinion bearing cup in the housing with the proper thickness of shims. Press the rear pinion bearing on the shaft.
2. Install the front bearing cup and shims, and front bearing.
3. Install the companion flange and, while holding the flange from turning, tighten the nut to a torque load of 200-220 lb. ft.
4. Check the pinion bearing pre-load with a spring scale and heavy cord wrapped around the companion flange. Pull on the spring scale. The torque required to rotate the pinion is 10-30 inch lbs. If not within these limits, add or remove shims from behind the front bearing to obtain the proper pre-load.
5. Remove the companion flange and install a new oil seal (well soaked). Reinstall the companion flange and tighten the nut to a torque load of 200-220 lb. ft.

Ring Gear, Replace

1. Install guide pins in every other hole in the ring gear. These pins can be made from 1½" long capscrews with heads cut off and ends slotted.
2. Make sure back face of ring gear and face of case are free of dirt and burrs and slip gear over pilot diameter of case.
3. Install every other ring gear bolt. Draw them up evenly and snugly so ring gear face is flush with face of case.
4. Remove guide pins and install remaining bolts.

Differential Carrier, Assemble

The differential bearings are adjusted by shims, Fig. 3. These shims also establish the ring gear position with the pinion. Therefore, backlash must be checked whenever a bearing adjustment is made.

The correct bearing adjustment is one which will provide a .015-.020" pinch fit when the differential unit is assembled into the carrier. To make the adjustment, install the bearing cones without shims and place the assembly in the housing with the bearing cups. Force the unit to one side and check the clearance between the bearing cup and differential case with a feeler gauge, Fig. 4. When the clearance is determined, select shims of this amount plus .015-.020" extra to establish the proper pre-load.

Remove the differential bearings again and divide the shims into two packs of equal thickness and install on each side and replace the bearings. Reinstall the unit in the carrier. This operation is made easier by cocking the bearing cups

Fig. 5 Method of correcting backlash between ring gear and pinion. Spicer axle

Fig. 6 Short heel contact. Move ring gear toward pinion

Fig. 7 Short toe contact. Move ring gear away from pinion

Fig. 8 Contact too low and narrow. Pinion should be moved away from center of axle

Fig. 9 Contact too high and narrow. Pinion should be moved toward center of axle

Fig. 10 Correct tooth contact. Gears making contact as shown give best results for quiet operation and long life

slightly when the differential is placed in the housing and then tapping them lightly with a mallet. However, when installing the differential in the housing, be sure the ring gear teeth mesh with the pinion teeth before tapping the bearings in place.

After the bearing cups are firmly in place, install the bearing caps. The bearing caps and gasket surface of the housing are marked with a horizontal numeral and on the other side by a vertical numeral. The position of the numerals should correspond when reinstalling the bearing caps.

Ring Gear & Pinion Backlash, Adjust

Mount a backlash gauge indicator on the carrier and start checking for the correct backlash between the ring gear and pinion. If the backlash is not within the limits of .004″ to .009″, it will be necessary to change the arrangement of the shims back of the bearings. Make corrections in backlash according to Fig. 6, bearing in mind that shims removed from one side must be installed on the opposite side so that the total shim thickness of the right and left side will remain unchanged, and the bearing adjustment undisturbed.

Gear Tooth Contact Pattern

Allowable variations in the carrier or drive pinion may cause the pinion to be too far in or out even when shimmed properly. Thus, the tooth contact must be tested and corrected as necessary or the gears may be noisy.

Paint the ring gear teeth with a light coating of red lead, white lead or prussian blue. Revolve the gears and observe the contact, referring to Figs. 6 to 10.

Steering Gear Section

STEERING GEAR

This steering gear, Fig. 1, is the cam and twin lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove, causing the lever arm to rotate the lever shaft. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and the cam where most of the steering action occurs.

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the lock nut adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are .002″, .003″ and .010″ thickness.
4. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the

Fig. 1 Ross cam and twin lever steering gear

rim. If necessary, remove or replace shims until the adjustment is correct.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then, starting from this point, count the number of turns required to reach end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but a slight drag should be felt in the mid-position only.
3. After proper adjustment is secured, tighten the lock nut and give the gear a final check for binding.

MODEL INDEX & ENGINE APPLICATION

ENGINE IDENTIFICATION—White service parts identification plate is attached to the left hand cab door. Stamped on the plate is the model of the engine, transmission, auxiliary transmission, rear axle and front axle. This represents only the equipment on the vehicle when it was shipped from the factory.

①—When checked with a 1″ wide feeler it should require a 7 to 10 lb. pull on a spring scale to withdraw the feeler past the piston.
②—Piston is properly fitted when it can be moved by applying pressure with one or two fingers.
③—For top ring, 2nd ring .012″.
④—When checked with ½″ wide feeler gauge, a pull of 3 to 8 lbs. is required.
⑤—Front bearing .0014–.0039″.

Engine Section

CYLINDER HEAD, REPLACE

Side Valve Engines

Cylinder heads should be tightened down by starting from the center and working outward from side to side and to the ends. Draw the nuts or bolts down evenly, repeating the operation until all are normally tight. After the engine has been run long enough to warm it up, a final tightening should be made in the sequence shown in Figs. 1 and 2 and to the torque given in the *Engine Tightening* chart.

Overhead Valve Engines

When removing a cylinder head a chisel or screw driver should never be used to pry it loose from the cylinder block. Use an eyebolt in the third or fourth spark plug hole (6-cyl. engines), lifting up on the eyebolt while tapping lightly around the edges of the head with a lead or rawhide hammer or mallet. Be sure all the head stud nuts or bolts have been removed before starting to remove the head.

In replacing the head, the stud nuts or bolts at the center of the head should be tightened first and then work outward from side to side and to the ends. Draw the nuts or bolts down evenly until all are normally tight. After the engine has run long enough to warm it up, make a final tightening with a torque wrench to the torque loads given in the *Engine Tightening Chart* and in the sequence shown in Figs. 3 and 4.

VALVES, ADJUST

All Engines

Adjust the valves to the clearances given in the *Tune Up & Valve Specifications* table. If the valves are to be adjusted warm, run the engine for about 30 minutes to normalize the expansion of all parts.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

①—30 ft.-lbs. for 14MM, 34 ft.-lbs. for 18MM.

VALVES, REMOVE

Side Valve Engines

After taking off the cylinder head, remove the valve chamber covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so that they can be identified as to the valve port from which they were removed.

Overhead Valve Engines

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

Fig. 1 Head tightening chart for side valve engine heads with 22 bolts

Fig. 2 Head tightening chart for side valve engine heads with 33 bolts

Sectional view of V8 engine

ROCKER ARMS

Overhead Valve Sixes

The valve mechanism is pressure lubricated from the rear camshaft bearing up through an oil passage in rear of block, through slot in cylinder head gasket to passage in head, up to and into the rocker shaft at rear support. The two tubular shafts on which the rocker arms are mounted are held in position by two terminal and five intermediate supports using seven of the bolts that secure the cylinder head to the block. The five intermediate supports are alike, but the two end supports are closed on the outer face, against which one end of the rocker arm shaft is inserted.

Oil holes in the rocker arms are drilled at a 10° offset angle from vertical toward the valve end of the arm. The arm has a split type bronze bushing. Oil holes in the shaft are drilled at right angles to the centerline of the shaft at top and bottom.

When installing new bushings in arms, drill hole in bushing after installation using hole in rocker arm as a guide. Be sure and clean off all burrs on inner side of bushing caused by drilling. When installing rocker arm cover make certain the two leather washers (nut gaskets) are properly in place.

CAUTION: Tighten the holding nuts firmly but not to a point of springing the cover.

Rocker Arm Bushing Data

Rocker Arm I.D., Bushing O.D. (Press fit)	1.1245 - 1.1255
Bushing I.D., finish after assembly	.9903 - .9913
Rocker Arm Shaft O.D.	.989 - .990
Nominal clearance	.0013 -

NOTE: To facilitate assembly of bushing and rocker arm, coat back of bushing with a mixture of white lead and oil before pressing into place.

VALVES, GRIND

All Engines

In grinding valves, the intake seats may be narrower than the exhaust because they are usually larger in diameter, thus providing a total seat area approximately equal to smaller exhaust valve with the wider seat. Also the less severe heat conditions do not require as large a seat area for heat dissipation purposes.

There are also objections to an excessively wide seat. In city or light delivery service, a wide seat collects carbon and particles of dirt that will produce variations or loss of compression, resulting in poor idle and possibly a loss of general performance and economy.

A wide seat in severe service, operating in the presence of dirt or an excess of carbon, will produce a badly pitted seat which may be just as detrimental to valve life as a too narrow seat. Under these conditions, a seat width to the minimum limit would possibly be better. However, the source of trouble (dirt, carbon) should be eliminated, making it possible to retain the wider seat.

VALVE ROTATORS

Some Side Valve Engines

The parts involved in the rotating

Fig. 3 Cylinder head tightening sequence for overhead valve sixes

Fig. 4 Cylinder head tightening sequence for V8 engines

Fig. 5 Free valve stem-to-cap clearance. Side valve engines

Super Mustang overhead valve six-cylinder engine used in Tilt-Cab models. Engine used in conventional models have a full-length oil pan sump

mechanism are special spring seat retainer, a pair of flat halfmoon keys, a close fitting cap located on the valve stem, and a specially constructed valve stem, Fig. 5.

In order to accommodate valve expansion, the valve lash must be maintained. When camshaft rotation causes this lash or clearance to be taken up, the cap on the valve stem causes the valve keys to lower the spring retainer, removing the load of the valve springs from the valve *before* the valve is raised from its seat. The clearance shown in Fig. 5 should be maintained between the end face of the valve stem and cap. This is the distance the spring retainer is lowered *before* the valve is moved. The slow valve rotating motion is caused by vibration of the valve, the flowing of exhaust gases around the valve head, and a slight rotation motion imparted to the valve by the valve spring.

Whenever valve work is done, check the clearance, using a special gauge which is available for the purpose. If there is no clearance, grind off the end of the valve stem. If the clearance is too great, grind off the open end of the valve cap.

If the special gauge is not available, a check for clearance can be made by holding the assembled valve and rotating mechanism in the hands. With one hand press down on the valve cap and with the other hand turn the valve. If the valve turns readily at least it indicates that there is clearance present.

Overhead Valve Engines

Increased exhaust valve life is accomplished in these engines by the use of "Roto Valve" mechanism which is a special valve spring retainer and cap located on the end of the valve stem.

In operation, the rocker arm striking the cap lifts the retainer first, thus taking the spring load off the valve before lifting it from its seat. When the valve is in the raised position, it is free to rotate due to the vibration of the system.

When checking valve clearances, the feeler gauge is placed between the cap and socket as there is no other flat surface in the valve train.

VALVE SEAT INSERTS

Since these inserts are too hard to reface by ordinary hand grinding methods, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and the valve guide pilot is a snug fit in order to assure a concentric finish. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert (if a suitable puller is not available), drill two holes at opposite sides of the insert but not all the way through. Then cut through the undrilled portion with a sharp chisel and remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the new insert with "dry ice" to obtain maximum contraction of the metal and place it in the recess. If necessary, the insert may be pounded in by using a round driver the same size as the insert and pounding on same with a hammer.

If a standard insert is too loose, an oversize insert should be used. Oversize inserts are $\frac{1}{16}$" larger than the standard and, therefore, the recess should be bored out $\frac{1}{16}$" to accommodate the oversize insert.

When installed, peen the block or head around the insert bore to insure it remaining in place.

VALVE SPRINGS

After taking out the valves, remove the springs and wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a suitable test fixture if one is available.

If a fixture is not available at least check the free length of each spring by standing it alongside a new spring.

Any spring that does not conform to the pressure specifications (see *Tune Up & Valve Specifications* table) within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should be scrapped.

Sectional view of 470A and 490A engines

VALVE GUIDES, REPLACE

All Engines

Clean the valve guides with a wire guide brush and clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

Check the clearance between valve stems and guides carefully. Excessive clearance between valve stems and guides will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Valve stem-to-guide clearance may be checked with special "GO" and "NO-GO" gauges. Lacking these, an alternate method is to take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance, it will be necessary to replace the guides that are worn as indicated by this test. If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, it is an indication that the old valve stem is worn and a new valve must be installed.

Fig. 6 Cutaway and exterior views of hydraulic valve lifter. Side valve engines

VALVE LIFTERS

Hydraulic Type

Fig. 6 illustrates the hydraulic lifter used in these engines. Because of the close fit between the cylinder and plunger, the plunger and cylinder should never be mis-matched.

Failure of a hydraulic valve lifter is generally caused by an inadequate oil supply or dirt. An air leak at the intake side of the oil pump or too much oil in the engine will cause air bubbles in the oil supply to the lifters, causing them to collapse. This is a probable cause of trouble if several lifters fail to function, but air in the oil is an unlikely cause of failure of a single unit.

Remove the lock ring from the top of the lifter body and slide the complete unit out of the bottom of the lifter bracket. Take out the cylinder and plunger. Remove the plunger from the cylinder by twisting plunger counter-

Fig. 7 Punch marks aligned for correct valve timing with No. 6 piston at top of its firing stroke. Overhead valve sixes

Fig. 8 Relationship of engine timing components. V8 engines

Fig. 6A Valve timing on all timing gear driven side valve engines

clockwise to release the spring on the plunger.

Wash all parts in clean kerosene. *Never use gasoline or other fast drying agents.* Wash cylinder thoroughly until ball check rattles in cylinder.

To assemble, insert plunger in body. Plunger spring should be locked into cylinder body by turning clockwise with a twist of the plunger. Insert the lifter in the lifter bracket.

Before installing valve lifters in the engine, note the following items to make sure lifters are assembled properly. And be sure they are installed in the original position.

1. Ball check should rattle when cylinder unit is shaken.
2. Plunger should bounce back when pressed quickly into cylinder and released.
3. Plunger spring should be locked into cylinder body with a twist of the plunger.
4. Cylinder should slide smoothly into lifter body when free of oil.

Do not attempt to fill lifters with oil before assembly as this will be done automatically when the engine is running. After servicing and replacing the lifters, measure the clearance between the end of the plunger and valve stem. The valve must be fully seated. Use a feeler gauge to check the clearance, which should be from .040 to .080″. If the clearance is more than .080″, grind in the valve seat just enough to obtain the proper clearance. If the clearance is less than .040″, carefully grind the end of the valve stem.

Overhead Valve Engines

These engines are equipped with barrel type lifters which can be lifted out from above after taking out the push rods. With this construction the oil pan and camshaft need not be disturbed.

TIMING GEAR COVER

Overhead Valve Sixes

Before removing the timing gear cover it will be necessary to remove the oil pan and take out the five fore-and-aft bolts between front oil pan arch and timing gear cover. Before removing cover bolts from front face, tap edge with soft hammer and lift off over two locating dowels.

TIMING GEARS

Side Valve Engines

Before removing timing gears be sure timing marks are legible. And when replaced valve timing will be correct if "X" marks on both gears are meshed as shown in Fig. 6A.

Overhead Valve Engines

Both timing gears are punch-marked to automatically establish valve timing. On six-cylinder engines the punchmarks are aligned as shown in Fig. 7 with No. 6 piston on top of its firing stroke.

On V8 engines valve timing is correct when timing gears are installed so that the timing marks on the gears are meshed. Fig. 8 illustrates the relationship of the parts.

TIMING CHAIN

55A Engine

The timing marks on both sprockets should be opposite each other and in line with the centers of both the camshaft and crankshaft.

CAMSHAFT & BEARINGS

Camshaft end play is controlled by a thrust plate just behind the camshaft gear. End play should be held to about .005″ and can be checked by forcing the shaft back to the limit of its end play and inserting a feeler gauge between the thrust plate and the front end of the shaft. If end play is excessive, install a new thrust plate.

On overhead valve engines, steel-backed, lead babbitt-lined split bearings are used.

On side valve engines, camshaft bearings must be installed in sets and line-reamed to provide the proper operating clearance. Be sure oil feed holes in bearings and block are aligned to assure adequate lubrication.

PISTONS & RODS, REMOVE

After removing the cylinder head and oil pan, examine the cylinder bores above

the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals.

Make sure rods and pistons are properly numbered so they can be reinstalled in their proper cylinders. It is advisable to install the caps on the rods to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

If the pistons and rods have factory markings to indicate their position in the cylinders, assemble and install them according to these marks, or according to the marks made during removal if they were not otherwise marked. Fig. 9 illustrates V8 assembly.

PISTONS, REPLACE

All Engines

When fitting a piston, wipe the cylinder wall clean with a cloth and insert the piston upside down in the bore (rings and pin removed). Use a feeler gauge which is long enough to extend the full length of the piston. The thickness of the feeler should be the same as the piston clearance given in the chart. With the feeler hooked to a spring scale, a pull of 6 to 10 lbs. should be required to pull the feeler past the piston.

The fit of the piston should be checked at different points in the cylinder bore. And after fitting, each piston should be stamped with a number or otherwise marked with the cylinder number to which it belongs.

Whenever a single piston is replaced in service, the new piston should match the weight of the old piston within ¼ oz. in order to retain balance in the engine.

CYLINDER SLEEVES

Overhead Valve Engines

Whenever piston or ring installation is to be made, check cylinder sleeve bores for scores, out-of-round and taper. If out-of-round .006″ or more or if taper wear is .006″ or more, sleeve should be replaced. Reboring of sleeves and use of oversize pistons is not recommended. In many cases sleeves can be pulled out by hand to remove from block. When tight, do not drive out by pounding with metal objects as sleeves may be damaged or block distorted.

If rings only are to be installed, prior to removing pistons, remove ridge at top of each cylinder wall. When performing this operation, use particular care not to cut beyond the diameter of the cylinder wall. Leave approximately .001″ stock at ridge and remove with a hone. Each cylinder should be honed to break the glaze and to provide a better surface for wear-in of the new piston rings.

Fig. 10 Cylinder sleeve installation. Overhead valve engines

The cylinder block must be thoroughly cleaned after completion of honing operations.

Drain and dry out block surrounding sleeve area to prevent dripping or seepage of water on bearings. If engine is installed in stand RS-C356, rotating block so that crankshaft is vertical will materially aid in keeping any water or grit off bearing surfaces. If re-ringing is done with engine in chassis, breaking glaze may be omitted due to hazard of grit getting into bearing surfaces.

Fig. 9 Correct assembly of pistons and rods. V8 engines

CAUTION: If engine is rotated to fully inverted position, make certain that any abnormally loose sleeves do not fall out of block.

With sleeves out of block, remove any rough external surfaces with emery cloth *from chamfers only* (above lower "O" ring area). Use only sandpaper to clean other adjacent surfaces of sleeve or block.

IMPORTANT: Always install new neoprene sealing rings ("O" rings) whenever changing or reinstalling a sleeve. Be particularly careful that "O" rings are installed without a twist, otherwise a leak is likely to develop around "O" ring seam. Coat sealing rings with clean hydraulic fluid or glycerine before installing on sleeve. Be certain top counterbore in block for flange of sleeve is clean before attempting to insert sleeve. Clean the seal lands in block and coat with hydraulic fluid or glycerine before installing sleeve.

Install sleeve and seal assembly in its position in lower diameter of crankcase by allowing sleeve to find its own seat, then with hand pressure on top of flange rotate sleeve right and left and quickly push in place, Fig. 10. *Do not force sleeve into block.*

When sleeve is seated check and make sure that top flange, extends .001″ to .005″ above block. If sleeve flange is below planed surface of block it will not be sealed and held in place by the cylinder head and gasket which may

then allow water seepage into the cylinder bore.

Shims of .003″ and .006″ thickness are available with which sleeve protrusion may be corrected to the allowable tolerance as shown in the following table.

Recommended Schedule For Shim Installation

Height Measured	Add Shim	Height Above Deck
.001″ above deck	None	.001″
.000″ even	.003″	.003″
.001″ Below deck	.003″	.002″
.022″ Below deck	.006″	.004″
.003″ Below deck	.006″	.003″
.004″ Below deck	.006″	.002″
.005″ Below deck	.006″	.001″
.006″ Below deck	.003″ & .006″	.003″
.077″ Below deck	.003″ & .006″	.002″
.008″ Below deck	.003″ & .006″	.001″
.009″ Below deck	.006″ & .006″	.003″
.010″ Below deck	.006″ & .006″	.002″

Whenever a sleeve height is adjusted by the use of shims, the resulting protrusion should be within .002″ of that of the adjacent sleeves if possible.

PISTON RINGS, REPLACE

When new piston rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with either end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

PISTON PINS, REPLACE

Piston pins are of the full floating type, being free to rotate in the piston bosses as well as in the connecting rod bushings at operating temperatures. Snap rings, located in the grooves in the piston bosses, prevent the pins from contacting the cylinder walls.

To fit a pin, heat the piston in a pail of boiling water until heated thoroughly. Then remove the piston and quickly insert the pin. A good fit is one which requires a slight push of the thumb to insert the pin.

ROD BEARINGS, REPLACE

Connecting rods are fitted with precision type bearings, held in position by locking lugs which fit into grooves cut in the rods and in the caps.

Bearing clearance may be checked with Plastigage, which is available at any auto parts jobber. Instructions for its use are furnished with the package.

Lacking Plastigage, use a piece of tough paper or shim stock ¾″ square which measures about .0005″ under the maximum allowable bearing clearance. Oil the shim on both sides and lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap nuts to the torque given in the table.

The clearance is correct if the rod can be moved endwise when tapped lightly with a hammer. If the rod can be moved endwise by hand, clearance is too great. On the other hand, if the rod will not move when tapped lightly with a hammer, not enough clearance is present.

Service Note

In checking bearing clearance, the White Company recommends the use of virgin lead wire. With this method, apply a thin film of SAE 20 engine oil to the bearing to be checked and place a piece of the lead wire (⅜″ long) on each end of the rod bearing crankpin, parallel to the centerline of the crankshaft. Then install the rod cap, rotating the crankshaft through a 15° arc as the cap nuts are being tightened. When the caps have been tightened to normal tension, free up the bearing by turning the crankshaft through a 15° arc and remove the cap and wire. Measure the flattened wire with a micrometer, which will be the clearance of the bearing.

MAIN BEARINGS, REPLACE

Insert type main bearings are used and may be replaced without removing the crankshaft. Main bearings should be replaced in sets and under no circumstances should they be filed or otherwise altered in an attempt to affect an adjustment.

Plastigage may be used to check the fit of bearings and instructions for its use are furnished with the package. The White Company, however, recommends the use of virgin lead wire to check the fit of bearings. This method is described under *Rod Bearings, Replace.*

CRANKSHAFT END PLAY, ADJUST

Side Valve Engines

Crankshaft end thrust is taken on the flanges of the center main bearing (front bearing on 55A engine). Through normal wear end play will seldom become excessive but whenever new bearings are fitted, check the end play by forcing the crankshaft to the limit of its end play and check the clearance with a feeler gauge. If end play is greater than .007″, install new thrust bearing shells. If clearance is less than .003″, the bearing flanges may be dressed down to obtain the desired result.

Overhead Valve Engines

On six-cylinder engines crankshaft end thrust is taken up on the front main bearing. On early models it is controlled by flanges on the upper half only of this bearing. Later models have thrust flanges on upper and lower halves.

On V8 engines crankshaft end play is controlled by flanges on the rear main bearing.

A quick check of crankshaft end play can be made by anchoring a dial indicator to the chassis back of the radiator with the indicator on the front of the crankshaft pulley. Throwing the clutch in and out will cause a forward movement of the crankshaft to the extent of its end play. Using a piece of 2 x 4 wood ahead of the pulley, pry the crankshaft back (with foot off clutch pedal).

If check shows end play in excess of .012″, immediate correction of the condition is absolutely necessary because if the engine is allowed to run with excessive end play it will destroy the highly polished face of the crankshaft against which the bearing thrust flanges ride. Ultimately, this polished surface will be scored to the extent that a new thrust bearing will wear out in a very few miles. When this condition is reached the only correction is a new crankshaft.

CRANKSHAFT OIL SEAL, REPLACE

Side Valve Engines

On some of these engines oil sealing at the rear main bearing is controlled by an oil slinger integral with the crankshaft and running in a groove leading into the oil pan. The end of the rear main bearing pipe extends below the level of the oil in the oil pan to prevent crankcase pressure from interfering with the return of the oil.

On other engines, in addition to the oil slinger, an oil seal, consisting of two pieces of special packing is used. One piece is installed in tne groove in the rear bearing cap and the other piece is installed in a similar groove in the cylinder block.

Position the rear bearing seal in the groove in the cylinder block. Lay an improvised mandrel in the bearing bore and strike the mandrel with a hammer to drive the seal into the groove. Install the seal in the bearing cap in a similar manner. Using a sharp knife, cut off both ends of each seal which project out of the grooves. When cutting off the ends of the seals, do not leave frayed ends which would prevent proper seating of the bearing cap if the ends should extend between cap and cylinder block.

Overhead Valve Sixes

To replace the rear oil seal it is necessary to remove flywheel, oil pan and oil pan rear arch.

Many cases of oil leakage at the rear of the engine are caused by seals being damaged before and during installation.

In handling this seal, be careful that the inner seal part is not touched by dirt from the hands. Inspect before installing. If it is the least bit dirty or has any grit on it, wash in oleum spirits before installing. Any slight piece of foreign material which might become imbedded in this seal will cause it to leak.

Make sure that the hub of the crankshaft which the seal contacts is absolutely clean, polished and not scored. Invariably when the flywheel is removed, the edge of the crankshaft hub is burred or scratched when freed from the recess where it sets into the flywheel. Be sure and remove all burrs on hub and hub chamfer, eliminating all sharp and jagged edges before fitting seal over crankshaft hub.

As the seal is an expanding fit, be particularly careful not to distort or break the edge when fitting it over the crankshaft hub.

Secure housing or retainer to block from rear with 4 cap screws and tighten. Install rear arch. Secure retainer to arch from front with 3 lower and 2 upper cap screws. First secure all cap screws finger tight. Tighten screws top to opposite bottom alternately. Tighten lower center last.

The rear oil seal lip should be coated with grease (not oil) prior to installation on the crankshaft hub. The grease should be applied to the hub as well as the seal lip in order to avoid wiping the lubricant off the hub when the seal is installed. The purpose of this procedure is to prevent the seal from running with insufficient lubrication and, therefore, becoming excessively hot before crankcase oil can reach it. This grease application will also facilitate sliding the seal over the hub. Use Lubriplate #320, or an equivalent which has a relatively high melting point.

When bolting the housing into place, put Permatex #2 in the cap screw holes to keep internal pressure from forcing oil out between the cap screw and hole threads.

V8 Engines

Oil sealing at the rear main bearing is controlled by a wick-type seal in the same manner as for some side valve engines outlined above.

OIL PUMP REPAIRS

Side Valve Engines

These pumps can easily be disassembled by taking off the upper drive gear and bottom cover, after which the internal parts can readily be removed. Be sure to examine the pump pressure ball check, spring and seat, and if these parts show wear, new parts must be installed.

Service Note

On some engines, the oil pump is the rotor type. It is easily disassembled but the following are several points which should be noted when the pump is serviced.

1. The end clearance should be held to .0015 to .0045″ on the inner rotor and .001 to 004″ on the outer rotor. These measurements are the difference between the depth of the counterbore in the body, including the gasket, and the length of the rotor. Always use a new gasket in assembling the pump.
2. The inner and outer rotor should have a tooth clearance of .002 to .010″.
3. The outer rotor outside diameter clearance should be from .003 to .010″. The clearance is measured between the outside diameter of the outer rotor and the inside diameter of the pump body.
4. Always install a new snap ring when the rotor has been removed from the shaft.
5. When assembled, the pump should turn finger free before installing on the engine.

Fig. 11 Installing oil pump on overhead valve sixes

Fig. 12 Sealed bearing type water pump

Fig. 13 Water pump with removable bearings

Service Note

On 110A, 120A, 140A, 150A, 250A, whenever the oil pump is removed, it is advisable to remove the ignition distributor as well, since it is driven directly from an extension of the oil pump shaft.

To install the pump, crank the engine until No. 1 piston is on its compression stroke and stop when it is on top dead center, as indicated by the timing mark on the flywheel. With the engine in this position, install the oil pump. Replace the oil pump extension shaft. With the tongue on the lower end of the shaft in mesh with the oil pump shaft groove, check the position of the groove in distributor end of the extension shaft. Location of the oil pump drive gears may not permit exact positioning of the groove (45 degree angle from centerline of crankshaft); however, make sure the pump gear is not meshing one or more teeth off the prescribed position.

Installation, 6 Cyl. Engines

When installing oil pump, distributor should be removed to prevent interference by distributor shaft tongue.

If engine has been completely disassembled, oil pump should not be installed until crankshaft, camshaft and timing gears have been installed. Install oil pump as follows:

1. Turn engine over to No. 6 firing position. Be sure marks on timing gears are aligned as shown in Fig. 7.
2. Place oil pump distributor drive slot in position shown in Fig. 11. Note that slot is offset and that narrow segment of drive end is at top and rotated to the right.
3. Install long studs in two bolt holes in crankcase as pilots. Place gasket on pilot studs. Slide pump assembly into position in crankcase being careful not to turn gear before it meshes with drive gear on camshaft. As oil pump gear meshes with camshaft drive gear it rotates counterclockwise approximately two teeth and slot then faces as shown in Fig. 11, installed position.
4. Mark No. 6 terminal position on distributor body and install distributor. Rotor should face No. 6 mark when distributor cap snap springs are in a line approximately parallel to cylinder block.

CAUTION: Do not tighten oil pump cap screws until distributor is installed. Check carefully to determine that dis-

tributor and oil pump assemblies rotate freely together after tightening pump fastenings.

WATER PUMP REPAIRS

Sealed Bearing Type, Fig. 12

This type pump is packed with lubricant at the time of assembly and requires no further lubrication. When disassembling, carefully note the arrangement of the seal parts so that correct assembly may be assured.

Never soak the shaft and bearing assembly in cleaning solvent because it will dissolve the lubricant. To clean the shaft and bearing, merely moisten a cloth with cleaning fluid and wipe away any surplus lubricant or other foreign matter.

Be sure the face of the housing against which the thrust washer turns is smooth and true. If not, smooth it up with a special water pump facing cutter.

Removable Bearing Type, Fig. 13

To service the pump, remove the fan pulley. Release the snap ring from the front bearing. Take off the rear cover plate. Press the shaft out of the impeller from the rear and remove the shaft and bearings as a unit. Press the shaft from the bearings, sleeve and slinger. Remove the seal from the impeller, noting the arrangement of the seal parts so that the new seal may be installed correctly.

Before assembling the pump, check the thrust face of the housing and if the surface is not smooth or true it should be smoothed up with a special water pump facing cutter.

To assemble the pump, apply a liberal quantity of grease to the bearings and to the shaft between the bearings. Then install the shaft and bearings in the housing as a unit. Press the impeller and seal assembly down onto the shaft, pressing it down just flush with the end of the shaft. Complete the assembly by installing the cover plate and fan pulley.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

Fig. 14 Ignition wiring details. V8 engines

Fig. 16 Gauging float level. Holley carburetors

HOLLEY CARBURETORS

Models 847-FS & 852-FFG

These carburetors are dual downdraft units incorporating an integral governor, Fig. 15. The governor throttle mechanism is part of the carburetor and has been designed to provide the needed power required for moving the throttle to governing speeds as controlled by a separately driven governor rotor. The combination of these two units give instant response and accurate governing.

The carburetor and governor can be cleaned and serviced with ordinary tools and the governor rotor can be serviced independent of the carburetor. *Do not under any circumstances apply compressed air to an assembled carburetor as to do so may rupture the governor diaphragm.*

Fig. 15 Holley 847-FS carburetor. Typical of 852-FFG

Fig. 18 Holley carburetor governor. Model 1174

Fig. 19 Vacuum adjustment. Holley 1174 governor

Fig. 17 Checking fuel level. Holley 885 carburetors

Fuel & Float Level

When checking the fuel level in an open vessel, under 4 lbs. (3 on 852) pump pressure the level should measure $\frac{11}{16}''$. The measurement is taken below the surface of the float chamber cover (gasket in place) to the level of the fuel. The level may be corrected by bending the float arm, Fig. 15.

The float level can be set when the air horn is off by gauging the distance between the bottom of the float and the flange surface of the air horn, Fig. 16. Holding the air horn upside down and the float in the closed position, measure the distance from the flange surface of the air horn to what would normally be the bottom side of the float (not the soldered seam). The correct distance should measure $1\frac{9}{32}''$ on 847 units and $1\frac{11}{32}''$ on 852 carburetors. Bend the float lever arm as required to correct the float level.

Idle Mixture

The idle mixture is controlled by the idle adjustment needles. Turning these needles in makes a leaner mixture and turning them out makes the mixture richer. Turn the needles in until they just touch the seats and back off one full turn.

When the engine has warmed up to operating temperature, alter the adjustment as required to obtain smooth performance. The range should be between 1 and 1½ turns.

Accelerating Pump

The quantity of the fuel discharged by the accelerating pump can be controlled by changing the position of the pump link in the throttle lever. Of the three different positions (marked 1, 2 and 3) number 2 is the average setting, number 1 is for summer and 3 is for winter operation.

Models 885-JJG & 885-JJSG

These units are dual concentric carburetors with all metering jets and passages grouped together and located in the center of the float bowl. The float bowl is a separate unit, being suspended inside the main body from the main body cover. With this design the fuel is kept cool by circulation of the main air supply around and under the float bowl.

Fuel & Float Level

When checking the fuel level in an open vessel, under 5 lbs. pressure the fuel level should be $\frac{19}{32}''$ on 885-JJSG and $\frac{5}{8}''$ on 885-JJG. Measurement is taken from the float chamber cover with gasket in place to the level of the fuel in the bowl.

The float level can be set accurately by gauging the distance between the bottom of the floats and the chamber cover surface. When setting the float level, it is important that both the "Open" and "Closed" position of the floats be checked, Fig. 17.

To gauge the "Closed" position of the floats, hold the float chamber cover upside down. Then measure the distance from the float chamber gasket to what would normally be the bottom side of the free end of the floats. The distance should be $1\frac{5}{16}''$ on both models. Measurement is taken with fuel inlet valve in the closed position and the float chamber cover gasket in place. To correct the float setting for this position, the float lever arms should be bent up or down to bring the floats within the established limits and thus correct the fuel level for best operation. Pushing the floats up or toward the float cover, raises the fuel level, and down or away from the cover lowers the level.

The "Open" position is gauged by raising the floats up until the float stop arm comes to rest against the inlet needle housing. Then measure the float setting in the same manner as for the "Closed" position. The distance should measure $1\frac{15}{16}''$ on 885-JJSG (1¼″ on 885-JJG) with the gasket in place and the float in

the position illustrated in Fig. 17. Corrections for this setting can be made by bending the stop arm on the float lever.

Idle Mixture Setting

The idle needle valve setting from the closed position is from ¾ to 1¼ turns open. Care should be taken not to jam the needles against the seat tight enough to groove the points. If this occurs, the needles will have to be replaced before a satisfactory adjustment can be made.

When the engine has been warmed up, turn one idle needle in until the engine starts to slow down, then turn it out until it again slows down. A point midway between these two will be very close to the correct idle mixture. Repeat this procedure for the other needle. When this is done, cross check by repeating both of the above procedures. The idle speed should be reset, if necessary, between the above operations.

CARBURETOR GOVERNOR

Holley Model 1174, Fig. 18

Used with Holley carburetors, this governor is a vacuum controlled device featuring all the advantages of a mechanical governor without lengthy and complicated linkage. Should it become necessary to make any changes, proceed as follows:

To adjust the governor cut-off speed, remove the seal from the screw on the side of the governor housing and remove the screw. Rotate the engine until the end of the governor rotor, which carries the adjusting screw, is in line with the hole from which the screw was removed. Turn the adjusting screw clockwise to increase or counter-clockwise to decrease governed speed.

Whenever the governor has been disassembled and serviced, after reassembling turn the adjusting screw clockwise until it stops, then turn it counter-clockwise three full turns. Final adjustment is then made after the governor has been assembled to the engine.

The vacuum adjusting screw, Fig. 19, regulates the rpm spread between the governor full load cut-off speed and the no-load engine speed. Turning the screw clockwise will decrease the rpm spread. Turning it counter-clockwise will increase the spread. Changing the position of the screw will change the average governor speed and this should be corrected by the rotor adjusting screw.

Clutch, Transmission & Rear Axles

LONG CLUTCHES

CF Type

This type clutch employs centrifugal force to increase the pressure against the pressure plate and clutch plate at higher speeds, in addition to using conventional spring pressure. The release levers are provided with small centrifugal weights which are integral parts of the levers. As the clutch rotates at high speeds, these heavy ends of the levers tend to move outward and exert additional pressure against the pressure plate.

Clutch Control, Adjust

Unless the clutch control linkage is removed, the only adjustment is the length of the clutch release rod.

This rod adjustment is made to obtain proper clearance and thus compensate for normal lining wear. With the foot pedal in its normal raised position, the length of the rod is adjusted to obtain a minimum of $\frac{1}{16}$" free movement between the working face of the clutch throwout bearing and the clutch release levers. This will represent a free movement of the clutch pedal of about 1½". Lengthen or shorten the rod to maintain free play at the pedal to insure $\frac{1}{16}$" clearance at the throwout bearing.

Clutch, Replace

When removing the clutch assembly, after removing the transmission, care should be taken to back out the six attaching screws about three turns at a time successively. This will prevent the clutch cover from being distorted by permitting the tension of the clutch pressure springs to be held by two or three screws.

Do not permit the weight of the transmission to hang on the driven disc for if it is bent it will necessitate excessive pedal travel to release the clutch.

Upon installing, always use a pilot shaft through the driven disc. When assembling the clutch to the flywheel, turn all attaching screws in finger tight. Then tighten with a wrench each screw not over two turns at a time. Go from one side of the clutch to the other until all attaching screws are tightened securely.

Clutch Service

The three release levers are properly set in a parallel plane and permanently locked at assembly. They will require no further attention during the life of the clutch, and they cannot be serviced. The pressure springs are set on asbestos base insulator washers where they rest on the pressure plate.

Long 13", 14" & 15" Models

This type clutch is a dry disc type in which pressure is exerted against the pressure plate by a series of coil springs. This pressure is augmented by six specially weighted clutch release levers.

Each of these levers, made of forged steel and mounted on needle roller bearings, is weighted at the outer end in such a way that the faster the clutch revolves the more pressure is exerted against the clutch plate. Thus the centrifugal force action supplements the normal spring pressure against the clutch plate, thereby increasing the torque transmitting ability of the clutch.

With this clutch, no internal adjustments are necessary to compensate for wear.

Clutch Service

Unless special clutch rebuilding equipment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced as follows:

1. Remove transmission and bell housing.
2. Using six ⅜-16 x 1¼" capscrews, screw them into the cover plate in the holes provided until the screw heads just bottom to hold the springs compressed.
3. Unfasten the cover plate from the flywheel.
4. Remove the driven disc.
5. Place the new disc on the flywheel with the short hub toward the flywheel.
6. Install the clutch assembly.
7. Push an aligning shaft (a spare transmission shaft will do) through the clutch hub and pilot bearing.
8. Tighten the cover-to-flywheel screws down evenly and securely, giving each a few turns at a time until all are seated.
9. Remove the aligning shaft and the six screws used to keep the springs compressed when clutch was removed.
10. Before attaching the transmission to the engine, check the release levers and bearing for clearance. Use care to see that the flexible oil tube does not rub against the cover plate.

Clutch Pedal, Adjust

Clearance between the clutch release bearing and clutch levers is made by loosening the lock nut and turning the adjusting bolt as required to provide 1¼" to 1½" free pedal travel.

Adjustment of the release levers in the clutch assembly should never be attempted unless the assembly is removed and placed on a clutch rebuilder.

Steering Gear Section

ROSS CAM & LEVER

These gears, Figs. 1 and 2, are the cam and lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove causing the lever arm to rotate the lever shaft. As an aid to easy steering the lever shaft studs which engage the cam are mounted on tapered roller bearings. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and the cam where most of the steering action occurs.

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the lock nut and adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are .002", .003" and .010" thickness.
4. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim. If necessary, remove or replace shims until the adjustment is correct.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then starting from this point count the number of turns required to reach end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but

a slight drag should be felt in the mid-position only.

3. After proper adjustment is secured, tighten lock nut and give the gear a final check for binding.

Stud Roller Bearing, Adjust

In most cases the foregoing adjustments will be adequate but it is sometimes necessary to adjust the stud roller bearing units as they should be preloaded at all times. A heavy drag should be felt when revolving the studs by hand. If a torque wrench is available the bearings should be adjusted so that the torque required to revolve the stud is as follows:

Lever Shaft Dia.	Torque, In. lb.
1 3/8"	3-4
1 1/2"	3-4
1 5/8"	4-8
1 3/4"	5-11

1. To adjust, remove lever shaft from housing, wash the bearings in solvent and blow dry with compressed air, using care not to spin the bearings. Lubricate the bearings with light oil.
2. Straighten out the prong of the locking washer to release the stud nut. Remove the nut and install a new locking washer.
3. While holding the stud nut from turning with a spanner wrench on the locking washer, tighten the nut as required to revolve the stud in accordance with the table above.
4. When proper adjustment has been secured, bend the prong of the washer against a side of the nut to keep it from turning.
5. Lubricate the bearings with gear oil and assemble the lever shaft in the steering gear housing.

Engine Section

CYLINDER HEAD

90AA, 91AA Engines

1. Remove all items which would interfere with the removal of the cylinder head.
2. Drain cooling system. Be sure to open drain cock in center of block beneath intake manifold. On 90AA engine, also open drain cock at bottom of water-tempered intake manifold.
3. Remove intake and exhaust manifolds.
4. Remove rocker arm cover (also push rod cover on 91AA).
5. Remove rocker arm shaft assembly.
6. Remove rocker arm cups (90AA) or valve caps (91AA) and identify for reassembly.
7. Grip push rods and snap them sideways out of lifter brackets. Identify push rods for replacement in original locations.
8. Unfasten and remove head.
9. Reverse the foregoing procedure to install the head and tighten down in the sequences shown in Figs. 1 and 2.

96A, 97A Engines

1. Remove all items which would inter-

Fig. 2 Cylinder head tightening sequence. 91AA engine

Fig. 1 Cylinder head tightening sequence. 90AA engine

Fig. 3 Cylinder head tightening sequence. 96A, 97A engines

Lubrication diagram for 98A engines

Lubrication diagram for 96A, 97A engines

fere with the removal of the cylinder head.

2. Drain cooling system. Be sure to remove drain plug located on right side of cylinder block toward the rear.
3. Remove intake and exhaust manifold with carburetor as an assembly.
4. Remove rocker arm cover.
5. Remove rocker arm shaft assembly.
6. Remove push rods and identify for replacement in original locations.
7. Unfasten and remove head.
8. Reverse foregoing procedure to install head and tighten down in the sequence shown in Fig. 3. *When installing intake and exhaust manifolds to cylinder head, loosen the three bolts holding the intake manifold to the exhaust manifold. This is required to maintain proper alignment.*

98A Engine

1. Drain cooling system.
2. Remove air cleaner.
3. Remove alternator.
4. Disconnect fuel lines and accelerator linkage at carburetor.
5. Disconnect water hose as required.
6. Remove intake manifold and carburetor as a unit.
7. Disconnect exhaust pipes at manifold flanges.
8. Remove ignition cables and rocker arm covers.
9. Unfasten and remove heads.
10. Reverse foregoing procedure to install the heads and tighten down in the sequence shown in Fig. 4.

ROCKER ARMS

90AA, 91AA Engines

1. Disassemble rocker arm shaft by removing the retaining pin or plug from one end of the shaft and sliding off the component parts.
2. Inspect shaft for wear. If "shoulders" exist, the shaft must be replaced. Blow out oil holes with air.
3. Examine rocker arms for cracks, condition of valve contact surface and worn bushings. Replace all defective rocker arms or any having over .005" clearance between shaft and arm.
4. Check rocker arm shaft supports for cracks or other damage.

96A, 97A Engines

1. Disassemble rocker arm shaft by removing bolts and retainers and sliding parts off.
2. Examine component parts for wear or damage as suggested for 90AA engines.
3. The rocker arms and shaft must be assembled as shown in Fig. 5.
4. Install the rocker shaft retainers between rocker arms so that they seat on rocker shaft and not on extended bushing of rocker arm.
5. When installing the assembly, it is imperative that the flat on the end of the rocker shaft be on top and pointing toward the front of the engine. *This is necessary to provide proper lubrication to rocker assemblies.*
6. The long rocker shaft bolt is installed in the bracket at the rear of the cylinder head.

98A Engines

1. If the rocker arm assemblies have been disassembled for cleaning, inspection or the installation of new parts, they should be assembled in the following manner.
2. Slide rocker shaft into bore of strut and at the same time engage intake rocker arm.
3. Install spring and engage exhaust rocker arm. Install remainder of rocker arms in same sequence.
4. Make sure that rocker shaft head bolt grooves line up with head bolt holes in rocker shaft strut. In addition, the plug hole in strut must also line up with hole in rocker shaft.
5. Tap in new rocker shaft plug.

Fig. 5 Rocker arm shaft assembly. 96A, 97A engines

VALVES, ADJUST

It is imperative that valve lash be held as close as possible to the correct specifications. If lash is excessive, it will cause the valve to open too late and close too early, resulting in valve bounce; the camshaft would also be subject to damage. If lash is set too close, the valve will open too early and close too late, causing burning and warping of valves, and rough engine operation.

On 90AA and 91AA engines, valve lash adjustment is accomplished by turning the adjusting screw in the rocker arm after loosening the lock nut. On 96A, 97A engines, valve lash is adjusted by turning the adjusting nut in the rocker arm.

On 98A engines, the adjustment is made at the self-locking rocker arm adjusting screw. The screw should have a minimum of 3 foot-pounds torque as it is turned. If less than this, replace the adjusting screw and, if necessary, the rocker arm.

On all engines, the adjustment should be made while the engine is running at hot idle speed.

VALVE ROTATORS

In the 90AA engine, both the intake and exhaust valve assemblies include positive rotators which revolve each valve a definite amount each time it

opens. In the 91AA, 96A, 97A and 98A, each exhaust valve has a positive rotator of the same type.

Before an engine is disassembled for valve grinding or major repair work, the performance of the rotators should be checked as follows:

1. With engine in vehicle, remove rocker arm covers.
2. Observe valve rotation with engine running at moderate speed. The valves should rotate at uniform and constant speeds.
3. Rotators that do not appear to function properly should be replaced.

VALVES, REMOVE

1. With cylinder head removed, take off exhaust manifold and rocker arm assemblies.
2. Use a suitable spring compressor to compress the valve springs.
3. Remove valve locks.
4. Release and remove spring compressing tool.
5. Remove springs and spring retainers. If burrs exist in lock grooves, file them off before removing valves.
6. Remove valves and place them in a board or rack with numbered holes so that they can be identified as to the valve port from which they were removed.

Internal parts for 96A, 97A engines

VALVE SPRING TESTING

Wash all springs with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 6, and according to the specifications given in the *Valve Data* chart. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

Fig. 6 Checking valve spring tension

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 7. If the assembled height is greater than the dimension given in the *Valve Specifications Chart*, install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

VALVE GUIDES

90AA, 91AA Engines

1. Clean the valve stem guides, removing lacquer or other deposits with a suitable guide cleaning brush.
2. Check guides for wear by using a "Go—NoGo" plug gauge, or a telescope gauge and a one inch micrometer.
3. Replace all valve guides that are worn over .3442" in diameter.
4. Remove guides, when necessary, by pressing them out from the combustion chamber side.

Fig. 7 Checking valve spring installed height

Fig. 8 Checking valve guide clearance

5. New guides should also be pressed in from the combustion chamber side, to the correct depth below the cylinder head face.
6. Depth is $1\frac{7}{16}''$ for 90AA engine. On 91AA engine, depth is $1\frac{3}{32}''$ for intake guide and $1\frac{11}{32}''$ for exhaust guide.

96A, 97A, 98A Engines

Valve guides in these engines are an integral part of the cylinder heads and, therefore, cannot be removed. For service, guide holes can be reamed oversize to accommodate one of three service valves with oversize stems (.005", .015" and .030").

Test the valve guides for wear as shown in Fig. 8. Install a suitable sleeve over the valve stem to hold the valve at working height in the head. Attach a dial indicator having valve stem at right angle with edge of valve. Move valve to and from indicator. Total movement should not exceed .012" on intake valves and .017" on exhaust valves. If tolerance is excessive, ream guide holes and install valves with overside stems. Always use a .005" reamer first, then (if necessary) a .015" reamer and finally a .030" reamer so the guides remain true in relation to the seat.

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

If refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}''$, otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the block for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition. If new valves guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing the seats has a valve guide pilot.

The valve seat width after refacing should be a liberal $\frac{1}{16}''$ for intake seats but not more than $\frac{3}{32}''$ in any case. The width of exhaust seats should be $\frac{3}{64}''$ to a liberal $\frac{1}{16}''$.

Test valves for concentricity with seats and for tight seating. Valves can be tested by lightly coating the valve face with prussion blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.*

After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the tests to see whether a full mark is obtained on the valve. *Both tests are necessary to prove that a proper seat is being obtained.*

VALVE SEAT INSERTS

90AA, 91AA Engines

Since these inserts are too hard to reface by the ordinary hand grinding method, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and that the valve guide pilot is a snug fit in order to assure a concentric finish. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert (If a suitable puller is not available, Fig. 9) drill two holes at opposite sides of the insert but not all the way through. Then cut out the undrilled portion with a sharp chisel and remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the new insert with "dry ice" to obtain maximum contraction of the metal and place it in the recess. If necessary, the insert may be pounded in by using a round driver the same size as the insert and pounding on same with a hammer.

If a standard insert is too loose, secure an oversize one. Of course, the recess should be bored out to accommodate the oversize insert.

When installed, peen the block around the insert bore to insure the insert remains in place.

Fig. 9 Valve seat insert puller

Fig. 10 Valve timing for 90AA engine

VALVE LIFTERS

The 90AA engine utilizes mushroom type valve lifters having a base larger than the bore in which they operate. This design makes it necessary to remove the camshaft in order to remove the lifters from below, if necessary.

On 91AA, 96A, 97A and 98A, barrel type lifters are used which are the same diameter throughout their length. When necessary, these lifters may be removed from above after removing the valve push rods.

PUSH RODS

Before installing push rods, inspect them for bends or twists, and examine the ball and cup ends for excessive wear. Any push rod that is defective should be replaced.

TIMING GEARS

90AA Engine

Before removing the timing case cover, it will be necessary to remove the attaching capscrews from the front oil pan arch and to loosen or remove the balance of the oil pan fasteners. Remove the cover screws, tap the edges with a soft hammer and lift cover off the two locating dowels.

Timing gears must be replaced in pairs, and gears marked similarly with respect to size should be used. Crankshaft and camshaft gears are furnished in standard, undersizes and oversizes. Gears marked "S" are standard; "U" undersize, and "O" oversize. Figures within the latter two letters, such as "1" or "2", would indicate the variation in thousandths of an inch from the standard size. Gears can be selected to give the desired fit.

Both gears can be removed with a puller, using the tapped holes provided for this purpose.

Installation—Crankshaft gear installation may be facilitated by heating it in oil. This will allow it to slide easily on the crankshaft. Light tapping may be required to seat the gear fully.

The camshaft gear may be tapped

Fig. 11 Valve timing for 91AA engine

lightly into place. However, do not allow the camshaft to bump the expansion plug at the rear as this could cause an oil leak. Be certain that the timing marks on the gears are in mesh as shown in Fig. 10.

Check the gear backlash with the gears assembled in place. Pry the teeth as far apart as possible with a screwdriver and check with a feeler gauge. If a .0015″ feeler gauge will not enter the gap between the teeth, clearance is not excessive.

TIMING CHAIN

91AA Engine

1. To remove chain and sprockets, remove nut and locking plate on cam sprocket.
2. Pull chain sprockets from crankshaft and camshaft evenly. This can be done by the use of small pry bars, being careful not to damage sprockets or chain.
3. When replacing, be sure to have the chain properly lined up as shown in Fig. 11. Then slide sprockets and chain onto crankshaft and camshaft evenly. *Be sure to hold the camshaft forward by installing a pry bar in the fuel pump opening, as failure to do this may loosen the plug at the rear of the cylinder block, causing an oil leak.*

96A, 97A Engines

1. Before removing the chain cover, loosen the oil pan bolts to allow clearance.
2. Use a puller to remove pulley.
3. Unfasten and remove cover.
4. If oil seal in cover is damaged, install a new seal. After installing the seal, try to insert a .0015″ feeler between the seal and cover. If seal is properly installed, feeler gauge cannot be inserted.
5. Remove lock bolt and washer from cam sprocket. Then pull cam sprocket and chain forward evenly so that chain slides off crankshaft sprocket.
6. If crankshaft sprocket requires replacement, it can be removed by using a three-jaw puller. When installing the crankshaft sprocket, make certain that the timing is toward the front.
7. To replace the chain, be sure to have the timing marks properly aligned as shown in Fig. 12.

98A Engine

1. Insert a suitable tool into the ignition distributor hole between timing gear and block. Install retaining bolt. This will lock camshaft in position during installation of sprockets.
2. With sprockets fitted into chain according to marks as shown in Fig. 13, lift chain and sprockets, keeping sprockets tightly in position in chain.
3. Slide both sprockets evenly over their respective shafts. Push sprockets firmly over keyways and into position.
4. Place straightedge across face of sprockets and carefully check alignment of timing marks, Fig. 13. Marks should be exactly in line.
5. Slide fuel pump eccentric over camshaft and down against sprocket. Be sure slot in eccentric engages top of gear key. Install cup washer and bolt and tighten to 35 ft. lbs.
6. Slide crankshaft oil slinger over shaft and up against sprocket (flange away from sprocket).
7. Before installing the cover, drive the old seal out and install a new one.
8. Slide chain case cover over locating dowels and, using a soft hammer, tap cover in place.
9. Install bolts and washers after coating with a suitable sealer. Tighten bolts to 15 ft. lbs. Install the short bolt at the oil filler pipe location.

CAMSHAFT & BEARINGS

90AA, 91AA Engines

1. With timing case cover removed, bring No. 1 piston to top dead center.
2. Remove screws retaining camshaft thrust plate to block. This can be done only with the cam gear removed. If thrust plate indicates scoring or wear, replace without question.
3. In 90AA engines, the mushroom type valve lifters must be raised as high in their bores as possible in order to remove the camshaft. This can be done with wire or spring-type clothespins. The valve lifters can be removed, if required, from the bottom of the block after camshaft and oil pan are removed.

Fig. 12 Valve timing for 96A, 97A engines

Fig. 13 Valve timing for 98A engine

4. On 91AA engines, the barrel type valve lifters are made accessible through the push rod chamber cover. Be sure to identify lifters for installation in proper location.
5. Remove fuel pump, allowing camshaft to be pulled from block.
6. If necessary to replace camshaft bushings, service bushings are available which require no reaming. Care should be exercised when installing new bushings to properly align oil holes.
7. Make certain No. 1 piston is on top dead center when reinstalling camshaft.

96A, 97A, 98A Engines

In order to remove the camshaft it is necessary to remove the fuel pump, distributor and oil pump in addition to the timing chain and sprocket. Also the valve lifters must be removed or raised so as not to interfere with removal.

If camshaft bushings are to be replaced, the engine must be removed from the vehicle. Service bushings are available which require no reaming. When installing bushings, make certain that bushing oil hole is in exact alignment with drilled oil passage from main bearing.

Install No. 1 camshaft bushing $\frac{3}{32}$″ inward from face of cylinder block on 96A and 97A engines.

PISTONS & RODS, REMOVE

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. Make sure rods and pistons are properly numbered so they can be reinstalled in the proper cylinders. It is advisable to install caps on rods to avoid mixing parts.

Fig. 14 Correct assembly of piston and rod. 96A, 97A engines

PISTONS & RODS, ASSEMBLE

90AA, 91AA Engines

If the pistons and rods have factory markings to indicate their position in the cylinders, assemble and install them according to these marks, or according to the marks made during removal if they were not otherwise marked.

96A, 97A Engines

Piston and rod assemblies must be installed with the notch on the piston head toward the front of the engine, and the oil hole in the connecting rod toward the manifold side of the engine, Fig. 14.

98A Engines

When installing piston and rod assemblies in the cylinders, the compression ring gaps should be diametrically opposite one another and not in line with the oil ring gap. The oil ring expander gap should be toward the outside of the "V" of the engine. The oil ring gap should be turned toward the inside of the engine "V".

Immerse the piston head and rings in clean engine oil and, with a suitable piston ring compressor, insert the piston and rod assembly into the bore. Tap the piston down into the bore, using the handle of a hammer.

Assemble and install the pistons and rods as shown in Fig. 15.

PISTONS, REPLACE

Before a honing or boring operation is started, measure all new pistons with a micrometer at points 90° away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is important that refinished cylinder bores are trued up to have not more than .0005″ out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at room temperature (70°) when the piston is checked for fit in the bore. Therefore, the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10° between the temperature of parts is sufficient to produce a variation of .0005″.

PISTON RINGS, REPLACE

When new rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the diameter of the bore. This is done with a "Glazebuster" or a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is to be fitted. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land and a false measurement of clearance will result.

Fig. 15 Correct assembly of pistons and rods. 98A engine

Fig. 16 Checking bearing clearance with Plastigage

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

PISTON PINS

90AA, 91AA Engines

If the bushing in the upper end of the connecting rod is worn and original pistons are to be re-used, an oversize piston pin may be used. These are available in .002″, .003″ and .005″ oversize.

Before installing the piston pin, the piston should be heated in some form of oven or in hot water to a minimum temperature of 160 degrees F. This will allow the pin to be thumb-pushed on through the rod and into place without distortion. The snap rings must be assembled in the grooves, making certain that they are fully seated.

96A, 97A Engines

Piston pins are a press fit in the connecting rod and a very light thumb push fit in the piston. Pins are furnished in standard size only. If excessive clearance is noted, both piston and pin should be replaced.

98A Engine

Piston pin fit in both the connecting rod and piston should be a thumb push fit with parts at normal room temperature.

Piston pins are supplied in standard and oversizes of .003″ and .008″. When using an expansion reamer to fit oversize piston pins, be careful and take a very light cut. Ream and try the fit; then ream and try again until pin can be pushed into piston or connecting rod as above.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the piston and rod assemblies merely by taking off the rod cap and replacing the upper and lower bearing halves.

The clearance between the bearings and crankshaft can be measured with Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing.

Fig. 17 Installing rear main bearing oil seal. 96A, 97A engines

2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the bearing, Fig. 16.
3. Reinstall the bearing cap and tighten the bolts to the torque value given in the *Engine Tightening* table.
4. Remove the bearing cap again and check the bearing clearance by measuring the width of the flattened Plastigage. The measuring strip is supplied in the same envelope which contains the Plastigage.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005" to .015" cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole, to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening* table.

CRANKSHAFT OIL SEAL

90AA Engine

The rear crankshaft oil seal is of the "spring" type which keeps the dust out and the oil in. This seal contacts the polished surface of the crankshaft flange, and is pressed into a seal retainer which bolts to the rear of the cylinder block. To replace worn seals, proceed as follows:

1. Remove capscrews attaching seal retainer to block.
2. Remove old seal with a seal driver which fits the seal.
3. Press in a new oil seal.
4. Examine the seal contact surface in the block carefully. Any scratches or other damage to this surface must be polished out before reassembly of the seal to prevent further damage and thus render it ineffective.
5. Mount oil seal and retainer to cylinder block.

91AA Engine

This engine uses the jute-packing type of rear seal. To replace this packing and reassemble the rear seal, proceed as follows:

1. Remove filler block and oil guard, the latter being the semi-circular die casting which fits in the cylinder block in a groove machined just to the rear of the main bearing.
2. Clean all surfaces and grooves thoroughly. If a scraper or wire brush is used, be careful not to scratch or gouge the sealing surfaces. All dried cement or other foreign material must be removed from these surfaces. Check filler block contact faces for flatness; if warped, replace block.
3. The jute packing, as received, has a diameter about ⅓ greater than the width of the grooves. This must be crushed in a vise, or otherwise flattened, narrow enough to be inserted in the grooves.
4. Press flattened packing in both filler block and oil guard as well as possible by hand. Then, using a piston pin, smooth hammer handle or other tool with a smooth rounded surface, iron this packing into the groove so that it is seated firmly and expanded to grip the sides.
5. With a sharp knife or razor blade, cut off the excess packing protruding from ends of the groove parallel to the surface of the casting, allowing it to protrude $\frac{1}{32}$".
6. To assemble to the engine, coat the outer or sealing surface of the oil guard with a non-hardening cement. Slide it into place around the crankshaft if engine is still assembled, or directly into the recess if the crankshaft is out. When the assembly is made as outlined, and the filler block assembled and tightened in place, and completed with a new oil pan gasket, there is no possibility of oil leakage developing at this point.

96A, 97A, 98A Engines

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing, Figs. 17, 18. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

Fig. 18 Installing rear main bearing oil seal. 98A engine

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PUMP

90AA Engine

This oil pump is assembled to the front main bearing cap, being held in place by the main bearing capscrews. The drive gear meshes with and is driven by the crankshaft gear (see Fig. 10). These gears have a specified .004-.008" drive or clearance fit which must be checked when reassembling the engine. Shims are available to increase the center distances of the oil pump and crankshaft gears to maintain this fit.

The pressure relief is located on the bottom of the pump body just below the drive gear. Pressure is controlled by a plunger and spring, and may be increased by assembling washers ahead of the cotter pin in the plunger bore.

Fig. 19 Installing oil pump on 91AA engine

91AA Engine

This oil pump is externally mounted and driven off a gear on the camshaft. A gear assembled to the upper end of the oil pump shaft is driven by a mating gear cut on the camshaft. A by-pass type of relief is built into the pump so that surplus oil is recirculated.

The oil pressure relief is located externally on the right side of the pump. Pressure is controlled by a plunger and spring, the latter being specifically for a certain range. The only adjustment variation is either to change springs, or assemble or remove washers from behind the present spring. Up to four washers are permissible.

Installation—When installing the oil pump on this engine, the distributor should be removed. If the engine is completely disassembled, the oil pump should be installed only after the crankshaft, flywheel, camshaft and timing gears.

1. Turn engine over to No. 1 firing position. Be certain timing mark on flywheel coincides with pointer on flywheel housing.
2. Position oil pump distributor drive slot as shown in Fig. 19. Note that the slot is offset and that the narrow segment of the shaft is to the top.
3. Place gasket on pump body face, using a small amount of grease to retain it.
4. Insert pump shaft into bore, using care to avoid turning gear before it meshes with drive gear on camshaft. As this occurs, the slot in the shaft will appear nearly horizontal when viewed down the distributor shaft bore.
5. Assemble retaining screws.
6. Chalk-mark the No. 1 terminal position on the distributor body and install the distributor. The rotor should point to this mark when it is installed.

96A, 97A Engines

This oil pump, Fig. 20, is of the rotor type, externally mounted and driven by the camshaft. Remove and repair the pump as follows:

1. Unfasten and remove pump from engine.
2. Press off drive gear, exercising caution to support gear in order to keep load off aluminum body. Remove pump rotor and shaft and lift out outer rotor.
3. Check flatness of cover by laying a straightedge across cover surface. If a .0015″ feeler gauge can be inserted between cover and straightedge, cover should be replaced.
4. Measure thickness and diameter of outer rotor. If thickness is less than .649″ and diameter less than 2.469″, replace outer rotor. In same manner, measure thickness of inner rotor. If less than .649″, replace inner rotor.
5. Slide outer and inner rotors into pump body and place a straightedge across the face (between bolt holes). If a feeler gauge of more than .004″ can be inserted between rotors and straightedge, replace pump body.
6. Remove inner rotor and shaft, leaving outer rotor in pump cavity. Press outer rotor to one side with fingers and measure clearance between rotor and pump body. If clearance is more than .012″, replace pump body.
7. Measure clearance between inner and outer rotors. If more than .010″, replace both rotors.
8. Check relief valve plunger for scoring and for free operation. If scored, replace. If relief valve spring is replaced, the same color should be used unless oil pressure is above or below normal. Standard spring is red, light spring is gray, and heavy spring is brown.
9. Install new oil seal rings between cover and body. Tighten attaching bolts to 130 inch lbs. and install pump to engine. Tighten pump attaching bolts to 200 inch lbs.

98A Engine

As shown in Fig. 21, this oil pump is the rotor type, similar to the one shown in Fig. 20. Inspect the pump in the same manner as outlined above but to the following specifications:

1. Clearance between cover and rotors should be .0015″; if more, replace cover.
2. If thickness of outer rotor measures less than .998″, or if diameter is less than 2.244″, replace outer rotor.
3. If thickness of inner rotor measures less than .998″, replace rotor.
4. If feeler gauge of more than .004″ can be inserted between rotors and straightedge, replace both rotors.
5. If clearance between outer rotor and pump body exceeds .012″, replace pump body.
6. If clearance between inner and outer rotors exceed .006″, install new rotors.
7. If relief valve plunger is scored, install new plunger.
8. If relief valve spring has to be replaced, install new spring of same color unless pressure is too high or too low. Use gray spring if pressure is too high; brown spring if pressure is too low. Red spring is standard.

Fig. 21 Oil pump and filter. 98A engine

Fig. 20 Oil pump and filter. 96A, 97A engines

WATER PUMP

90AA, 91AA Engines

Disassemble, 90AA

1. Remove bolt from impeller hub and with a puller remove impeller from shaft. *Do not drive or pound on pump shaft or carbon seal on shaft will be damaged.*
2. Remove impeller snap ring and remove seal from impeller hub.
3. If shaft is to be removed, loosen set screw and, with a puller, pull fan hub from shaft.
4. Remove snap ring and press shaft and bearing assembly out of pump body toward the front end.

Disassemble, 91AA

1. Pull fan hub from shaft, Fig. 22.
2. Remove pump from engine.

Fig. 22 Water pump. 91AA engine

Fig. 23 Water pump. 96A, 97A, engines

3. Remove pump cover by taking out countersunk screws.
4. Use puller to remove impeller. *Do not attempt to drive pump shaft out through rear of housing as housing will be ruined.*
5. Remove seal and water shedder.
6. Remove lock ring holding shaft and bearing assembly in body. Then force shaft out of body with a lead hammer or arbor press.

Reassemble, 90AA, 91AA

1. Reassemble pump, replacing worn or damaged parts and reverse disassembly procedure. Seal contact surface must be smooth and flat. Bushing should be replaced if scored or cut, but may be refaced and polished for further use if not excessively worn or grooved.
2. Use thick soapsuds on both seal and shaft when assembling to prevent damage to seal.
3. Mount pump on engine using a new housing gasket.

96A, 97A Engines

This water pump, Fig. 23, has an aluminum casting and is not serviceable. If pump is defective, replace with a new one.

1. Loosen drive belt adjusting strap and move alternator toward engine.
2. Remove fan, spacer, pulley and belt.
3. Remove pump inlet hose and heater hose (if equipped).
4. Remove clamp from by-pass hose.
5. Remove pump body-to-housing bolts and push pump body down off by-pass hose.
6. Installation is made in reverse order of removal, using the two long bolts above and below the inlet hose. Tighten bolts to 30 ft. lbs.

98A Engine

Disassemble, Fig. 24

1. Place pump in a vise.
2. Break away plastic impeller from metal insert.
3. Use puller to remove insert.
4. Place pump in arbor press, front side down. *Apply pressure completely around mounting flange to avoid breaking pump housing.*
5. Press water pump shaft and bearing assembly out through front of pump and discard.

Assemble

1. Press new pump shaft and bearing assembly in through front of housing until shoulder of bearing is 3/32" below machined surface of housing. *Press on outer race only. Pressing on shaft will damage bearings, making pump noisy.*
2. Reface pump seal seat.
3. Install new seal and retaining washer. When inserting impeller on shaft, be sure flats on impeller interlock with lugs on thrust washer. Support hub end of shaft when pressing on impeller to avoid damaging bearing.
4. Support impeller end of pump shaft and press pump hub on shaft until it is assembled to 21/64" between front end of shaft and front face of hub.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

ZENITH CARBURETOR

Before making any adjustments on the carburetor, it is important that the breaker points and spark plugs are in good condition and properly set. The ignition timing should be checked and the valves operating properly.

Check all carburetor body and flange screws for tightness and make sure there are no gasket leaks, Fig. 25.

Float Level

As shown in Fig. 26, measure the distance between the bottom of the float and the machined surface of the casting. Hold the casting, without gasket, upside down as shown. With float closed, distance indicated should be 1 31/64". To change the float setting, bend the float lever (close to float body) as required.

Idle Speed & Mixture Adjustment

The idle adjustment should be set to the highest and steadiest vacuum reading with a vacuum gauge. Idle speed is regulated by the throttle stop screw, Fig. 25. Idle mixture is controlled by the idle ad-

Fig. 24 Water pump. 98A engine

Fig. 25 Zenith carburetor

Fig. 26 Checking float level on Zenith carburetor

Fig. 27 Carburetor governor adjustment

justment needle. Turning the needle clockwise increases the suction on the idle jet and causes a richer mixture. Turning the needle counter-clockwise causes a leaner mixture.

Accelerating Pump

If the engine does not accelerate properly, remove the air horn assembly and operate the pump with the carburetor bowl full of fuel. Force the pump piston down in its cylinder and note if the air vent check valve leaks. Repeat this operation, noting if the check valve leaks, allowing fuel to be forced back into the fuel bowl through the channel leading from the bottom of the pump cylinder back into the bowl. Repeat this operation again and observe the discharge of fuel at the accelerating jet. If the system is in good condition, a fine, solid, round stream will flow from the discharge nozzle.

Intermediate Operation

If trouble is encountered during intermediate speeds, check all gaskets for tightness. Remove and clean main jet, passages and main discharge nozzle with compressed air.

High Speed Operation

For high speed complaints, check the power valve and high speed restrictions as well as the main jet. Check the fuel pump pressure to see if it is sufficient to maintain proper fuel level in bowl. Float travel should also be observed for full opening of the float needle valve. The vacuum piston should fit properly in place and operate satisfactorily with no air leaks between piston and intake manifold.

CARBURETOR GOVERNOR

If smooth accurate governor action is to be obtained, friction of the throttle shaft and its bearings must be avoided. Most governor failures are due to the accumulation of carbon on the throttle shaft bearings.

Many governor failures can be temporarily corrected without complete disassembly of the carburetor and governor by the application of a good penetrating oil to the throttle shaft bearings. These can be reached by removing the carburetor and applying penetrating oil to the throttle shaft openings on the inside of the throttle body bore. Use care when applying the oil as excessive use will increase carbon formation.

Speed Adjustment

1. Warm up engine to normal operating temperature.
2. Remove seal wire and large seal plug, Fig. 27.
3. To increase speed, turn main spring adjusting screw clockwise; to reduce speed, turn counter-clockwise. *If governor does not show definite response to changes of ¼ to 1 full turn, it indicates a defective governor.*
4. After adjustment has been made, install seal plug and wire.

Surge Elimination

Surge is a condition of intermittent increase and decrease of engine speed. If a surge has developed or the governor is too sensitive, adjust as follows:

1. Remove seal wire and small seal plug, Fig. 27.
2. Turn compensating spring block adjusting screw ¼ turn counter-clockwise until surge is overcome.
3. Install seal plug and wire.

Slow Governor Correction

If the governor does not respond quickly enough when the governed speed is approached and the action can be considered "lagging" or "flat", adjust as follows:

1. Remove seal wire and small seal plug, Fig. 27.
2. Turn compensating spring block adjusting screw clockwise until "lag" or "flatness" is overcome. *Do not change adjustment more than ½ turn at a time without checking performance of vehicle on the road.*
3. After adjustment has been made, install seal plug and wire.

Clutch, Transmission, Rear Axle, Steering Gear

CLUTCH

The clutch, Fig. 1, is a dry, single plate type with a mechanical vibration damper. The clutch release bearing is of the thrust ball bearing type, prepacked and, therefore, requires no further lubrication. The clutch shaft pilot bearing is also of the ball bearing type, packed with lubricant at assembly, and requiring no further attention until made accessible when the clutch is being serviced.

1. Disconnect speedometer cable, hand brake lever control, propeller shaft and any other supplementary item necessary for transmission removal.
2. Remove transmission and bell housing.
3. Remove flywheel-to-clutch capscrews, turning them a little at a time until spring tension is relieved, and remove clutch and clutch disc. *If the same clutch is to be reinstalled, be sure to mark flywheel and clutch cover for reassembly in the original position to preserve the balance of the assembly.*
4. Install the new clutch in the reverse order of removal and adjust pedal free play.

Pedal Free Play, Adjust

Proper clearance between clutch release bearing and clutch levers is obtained by removing the clevis pins at the lower end of the release cable. Loosen the clevis lock nut and rotate the clevis as required to obtain 1" free play in the pedal.

TRANSMISSIONS

Figs. 1 and 2 illustrate the transmissions used in these trucks. See the Warner Transmission chapter for service procedures.

REAR AXLE

Axle Shaft, Remove

1. Raise vehicle and place stand jacks under rear axle housing.
2. Remove wheel and brake drum.
3. Remove four nuts from bearing retainer bolts on inside of axle flange.
4. Attach axle shaft puller and remove axle shaft and bearing assembly.
5. Install bolt and nut to hold brake backing plate on axle housing.

Bearing or Oil Seal, Replace

1. With a chisel, nick soft ring next to bearing and remove ring. The

Fig. 1 Warner T87E (White 304B, 305B) three speed transmission. See the Warner Transmission Chapter for service on this unit

Fig. 2 Warner T98 (White 426B) four speed transmission. See the Warner Transmission Chapter for service on this unit

ring need not be split, only nicked deep enough to allow removal.

2. Install a suitable press plate between axle flange and bearing and press bearing from shaft.
3. To replace oil seal, pry it out of housing with screwdriver.
4. Install new seal.
5. Install new bearing, pressing it on so it seats on the shaft against shoulder. Bearing retainer must be on axle shaft before bearing is installed.
6. Install new bearing retainer ring, being sure ring seats against bearing.

Axle Shaft, Install

1. Insert five new bolts and force heads down to flange on new axle.
2. Peen end of shoulder on bolts into countersink around bolt holes in flange.
3. Install new bearing as outlined above.
4. Remove temporary nut and bolt holding brake backing plate in place.
5. Install new retainer gasket.
6. Install axle shaft in housing. Outer race of bearing must seat against shoulder in axle housing.
7. Install nuts and washers on bearing retainer bolts and tighten securely.
8. Install brake drum and wheel.

Rear Axle Assembly, Replace

Inasmuch as the axle tubes are pressed into the differential carrier to form a one-piece housing, the rear axle assembly must be removed from the chassis when it becomes necessary to overhaul the unit.

1. Raise vehicle from floor and support with stand jacks under frame side rails.

Fig. 4 Spicer rear axle adjustments

2. Remove rear wheels.
3. Split rear universal joint.
4. Disconnect parking brake cable from equalizer rod and unfasten brake cable brackets from frame cross member.
5. Disconnect hydraulic brake line connection at rear axle housing.

STEERING GEAR

When making adjustments on the steering gear, Fig. 6, free the gear of all load, preferably by disconnecting the drag link from the steering arm, and loosen the instrument panel bracket clamp on the steering gear jacket tube. If the ball thrust bearings on the cam must be adjusted, make this adjustment first before making the side adjustment to the lever shaft stud in the cam groove.

1. Referring to Fig. 7, loosen the housing side cover adjusting screw to free the studs in the cam groove.
2. Adjustment should be made so there is a very slight drag but not so much that the steering wheel cannot be turned from one extreme to the other by lightly gripping the wheel rim with thumb and forefinger.
3. Unscrew the four screws and raise the housing upper cover to permit removal of shims.
4. Clip and remove a thin shim or more as required and draw cover down tight against shims.

Fig. 3 Disassembled view of Spicer rear axle

5. Test as outlined in Step 2 and if necessary, remove or replace shims until adjustment is correct.

Lever Shaft Stud, Adjust

1. Backlash at this point shows up as end play of lever shaft, also as backlash at steering wheel and at ball on steering arm.
2. The groove is purposely cut deeper in ends of cam than at mid-position. This produces a high range through

Fig. 5 Ross steering gear assembly

Fig. 6 Steering gear adjustments

mid-position and makes grooves narrower through this range. This permits take-up of backlash in mid-position, after normal wear of groove, without causing a bind in the ends.

3. Adjust to this mid-position high range only. Play in end position is not objectionable.
4. Tighten side cover adjusting screw until a very slight drag is felt through the mid-position when turning steering wheel slowly from one extreme position to the other. *Steering gear must not bind in any position. Only a very slight drag should be felt. A closer adjustment will not correct steering looseness caused by wear in other steering gear units, but will damage parts and impair operation.*
5. When proper adjustment has been made, tighten locknut and check adjustment.
6. Make sure steering gear arm is tight on splined lever shaft and that lockwasher and nut are tight also.

Engine Section

CYLINDER HEAD, REPLACE

All Engines

Before the cylinder head is installed, make certain that all dirt and carbon is removed from both the head and block. File or hone all high spots.

Use a torque wrench when tightening down cylinder heads. Uneven or excessive tightening of nuts may distort cylinder bores, causing compression loss and excessive oil consumption.

Tighten cylinder heads in the sequence shown in Figs. 1 to 4, tightening them a little at a time in the proper order a couple of times around before final tightening to the torque values given in the *Engine Tightening Chart*. After the engine has warmed up to operating temperature, recheck the torque and tighten as required.

On F-Head engines, be sure to check intake valve operating clearances after the final tightening.

Service Note

Tightening cylinder heads on F-head engines without removing rocker arms may be accomplished with a wrench having an $\frac{11}{16}''$ box on one end and a $\frac{1}{2}''$ square box on the other end. This, together with a torque wrench will do the job.

Accurate alignment of the cylinder head, gasket and block on L6-226 engines is required to prevent gasket failure. Two cylinder head bolt holes, at opposite corners of the head (positions 24 and 26 in Fig. 4) have a slightly smaller diameter that the other holes and can be used for guide pins.

The guide pins can be made by cutting the heads off two cylinder head bolts. Cut slots in the end from which the heads were removed to install and then remove the guide pins.

The torquing sequence for the head bolts is shown in Fig. 3.

OHC 6-230 Engine

1. To remove head with timing chain cover installed, first take off rocker arm cover.
2. Install camshaft sprocket removal and installation tool on rocker arm cover studs, Fig. 5. Fasten with rocker arm cover nuts. Install hook of removal tool in the sprocket and tighten the nut to relieve the tension on the camshaft.
3. Remove fuel pump eccentric from camshaft sprocket.
4. Pull forward on camshaft sprocket to remove it from pilot on camshaft. With sprocket still engaged in timing chain, release tension on tool by loosening nut. Gently allow sprocket to rest on bosses in timing chain cover. *Caution: Do not turn over engine when sprocket is removed from camshaft and is resting on bosses in cover. This will severely damage cover. Do not attempt to remove camshaft sprocket from timing chain since this will upset the valve timing.*
5. Disconnect lubrication tube from head and block.
6. Remove cylinder head bolts.
7. Lift off head assembly.
8. Reverse the removal procedure to install the head. Position the all-metal head gasket on the block so that the coolant ports and vent ports are properly aligned. Use no sealer or other compound on the gasket. When head is installed, tighten it down in the sequence shown in Fig. 4.

Fig. 1 Head tightening chart on 4-cyl. L-Head engines

Fig. 2 Cylinder head tightening sequence. Four-cyl. F-head engines

Fig. 3 Cylinder head tightening sequence. 6-226 engine

Fig. 4 Cylinder head tightening sequence. 6-230 engine

ROCKER ARM STUDS

OHC 6-230 Engine

If any of the rocker arm studs are worn, distorted or have damaged threads, they may be pressed out of the camshaft bearing deck. Press the nut stud into place until it is firmly seated in cam bearing support deck.

ROCKER ARM SERVICE

F-Head Engines

To remove the rocker arm assembly, proceed as follows:

1. Remove carburetor air cleaner.
2. Disconnect spark plug wires.
3. Drain cooling system.
4. Remove rocker arm cover.
5. Remove rocker arm bracket screws and lift off rocker arm assembly.

Before disassembly, mark rocker arms, brackets and shaft so they can be reassembled in the original positions.

Sludge and gum formation in the rocker arms and shafts will restrict the normal flow of oil to the rocker arms and valves. Each time the rocker arm and shaft assemblies are removed they should be disassembled and thoroughly cleaned.

When disassembling rocker arms, place all parts on the work bench in their proper sequence to insure correct assembly.

Clean all sludge and gum formation from the inside and outside of the shaft. Clean oil holes and passages in the rocker arms and shafts. Clean the oil connector. Inspect the shafts for wear.

Check the ball ends of the rocker arms to be sure they are not pitted or rough. If used in this condition, it will be difficult to maintain valve clearances.

VALVES, ADJUST

L-Head Engines

The valves may be adjusted when the engine is at normal room temperature. Crank the engine over until the valve to be adjusted is fully closed. Hold the lifter body with a tappet wrench to prevent it from turning. Then turn the tappet adjusting screw until the proper clearance is obtained. Measure the clearance with a feeler gauge and, after adjusting one tappet, proceed in like manner with the others, being certain that the valve being adjusted is fully closed.

In addition to the conventional method of adjusting tappets by locating the distributor rotor and then adjusting the tappets by following the firing order of the engine, the following method may also be used:

Four-Cylinder Engines

Valves Fully Raised	Adjust Tappets
1 and 3	6 and 8
2 and 5	4 and 7
6 and 8	1 and 3
4 and 7	2 and 5

Six-Cylinder 226" Engine

Valves Fully Raised	Adjust Tappets
1 and 3	10 and 12

Lubrication diagram for F-Head four cylinder engine

Lubrication diagram for Overhead Camshaft engine

8 and 9	4 and 5
2 and 6	7 and 11
10 and 12	1 and 3
4 and 5	8 and 9
7 and 11	2 and 6

4-Cyl. F-Head Engines

The exhaust valves (in block) may be adjusted in the same manner as outlined for L-head engines. However, the intake valves may best be adjusted with the engine running after it has warmed up to operating temperature.

If the cylinder head has been tightened, be sure to recheck intake valve clearances and adjust as required.

OHC 6-230 Engine

The adjustment may be made when the engine is either hot or cold. *Caution: Do not attempt to remove the rocker arm cover to adjust valve clearance when the engine is running. Always shut down the engine before removing the cover.*

Fig. 5 Camshaft sprocket removal and installation tool for use when removing cylinder head and timing chain. 6-230 engine

1. Remove rocker arm cover.
2. Turn engine over until No. 1 piston is at top dead center. This can be determined by checking the position of the No. 1 cam. When the associated piston is at top dead center, the nose of the cam points to the 6 o'clock position.
3. Insert a feeler gauge between the rocker arm and the top of the valve stem.
4. Use a socket wrench to adjust the clearance. Turning the rocker arm nut clockwise decreases the clearance; counterclockwise increases the clearance.
5. Adjust the valves in this manner for all cylinders, setting the associated cam nose to the 6 o'clock position before adjusting.

VALVES, REMOVE

OHC 6-230 Engine

1. After cylinder head is removed, position cylinder head on blocks to provide hand clearance under the assembly.
2. Remove valve springs. Use hand pressure to hold the valve while compressing the spring, Fig. 6.
3. Remove and discard valve guide seal from top of valve guide.
4. Remove all valves and place them in a numbered rack to make sure each valve will be reassembled in the same valve seat from which it was removed.

L-Head Engines

After removing the cylinder head, take off the valve chamber covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so they can be identified as to the valve port from which they were removed.

Fig. 6 Compressing valve springs. The air hose shown is attached to an air pressure adapter inserted into a spark plug hole to keep the valve closed when replacing a valve spring with the cylinder head installed. 6-230 engine

F-Head four-cylinder engine

F-Head four-cylinder engine

F-Head Engines

Follow the same procedure in removing the exhaust valves from these engines as outlined for L-head engines.

In removing the intake valves from the head a suitable fixture is available which holds the valves closed and compresses the spring at the same time.

VALVES, GRIND

All Engines

In refacing valves, take off the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced.

Inspect the valve seats in the block and head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed before refacing the seats if the equipment used has a valve guide pilot.

The valve seat width after refacing should measure not more than $\frac{5}{64}$ in. The width may be checked by placing a scale across the face of the seat.

A simple check can be made to prove the fit of the valve in the valve seat by spreading a thin film of Prussian Blue on the valve face and then inserting the valve into the valve seat. With hand pressure, rotate the valve $\frac{1}{4}$ turn and then remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer of Prussian Blue will indicate an inaccurate valve and valve seat refacing operation.

VALVE SPRINGS

All Engines

After taking out the valves, remove the springs and wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check valve spring pressure on a spring testing fixture if one is available. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Valve Data* chart within 10 per cent should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded.

VALVE GUIDES

All Engines

After the valves and springs have been removed, clean the valve guides with a wire brush, and clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads, as well as the gum which might have accumulated on the stems.

Check the clearance between the valve stems and guides carefully. Excessive clearance between the valve stem and guide will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

To check valve stem-to-guide clearance, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance, it will be necessary to replace the valve guide. If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

If it is necessary to replace the valve guides, the old guides can be driven out with a special driver which is available for the purpose. However, in lieu of the driver, the guides can be pulled out by using a suitable piece of pipe together with a long bolt and suitable washers.

When replacing the guides, maximum engine performance can only be secured when the guides are installed correctly, Figs. 7 and 8.

VALVE LIFTERS

All Engines

These lifters are of the mushroom type operating in guide holes cast in the block.

Fig. 7 Position of valve guides in 4-cyl. L-Head engines

This means that the camshaft will have to be removed from the engine if valve lifters require replacement.

Whenever the camshaft is removed, inspect the faces of the lifters where they contact the cams and replace any that are scored, rough or cracked. Check the clearance of the lifters in the guides, replacing those that have worn excessively. Oversize available is .004 in. and the guides must be reamed to accommodate them.

TIMING CASE COVER

4 Cyl. Engines

1. Drain cooling system.
2. Remove radiator and grille or guard.
3. Remove cylinder head, valves and springs.
4. On L-head engines, remove manifolds.
5. Remove fuel and oil pumps.
6. Remove oil pan.
7. Remove crankshaft pulley.
8. Remove fan assembly.
9. On CJ-2A and CJ-3A, remove nuts from front engine support.
10. Remove engine front cover.
11. Remove camshaft gear and thrust plate.
12. Tie valve lifters up to their highest point of travel with string wrapped around the adjusting screws and attach to manifold studs. Spring clip type clothespins or small "C" clamps may also be used.
13. On CJ-2A and CJ-3A, raise front of engine until camshaft will clear front crossmember.
14. Remove camshaft from engine.
15. To install, reverse foregoing procedure and set valve timing as shown in Fig. 9.

Fig. 8 Position of valve guides in 4-cyl. F-head engines

Fig. 9 Valve timing on four-cylinder engines

"6-226" Engines

1. Drain cooling system.
2. Remove radiator.
3. Remove vibration damper.
4. Remove timing chain cover.
5. Remove timing gears and chain.
6. Remove fuel pump.
7. Remove cylinder head.
8. Remove oil pan and oil pump.
9. Remove valves and springs.
10. Hold valve lifters up with spring type clothespins or string to prevent them from interfering with camshaft as it is being withdrawn.
11. Unfasten camshaft thrust plate from cylinder block and withdraw the camshaft.
12. To install, reverse removal procedure and set valve timing as shown in Fig. 10.

OHC 6-230 Engine

Removal

1. Remove hose clamps and hose from water port of chain cover.
2. Remove bolts that secure cover to front engine plate.
3. Remove cover, lifting eye and cover gaskets.
4. Slide oil slinger and oil pump drive gear from crankshaft.

Fig. 10 Valve timing on 6-226 engine

Fig. 11 Measurement for limit of timing chain wear. 6-230 engine

Installation

1. Apply a thin coat of gasket paste to both sides of cover gaskets and position gaskets on cover. Make sure Woodruff key, oil pump drive gear and oil slinger are installed on crankshaft.
2. Assemble sleeve and O-rings and install in oil port in cylinder block.
3. Lubricate oil pump push rod and install in chain cover.
4. Position chain cover on front engine plate and secure with bolts.
5. Be sure lifting eye is installed on upper right corner of front engine plate and generator brace on upper left of cover.

Front Oil Seal

1. After timing chain cover is installed,

Fig. 12 Valve timing marks for 6-230 engine

check crankshaft to make sure it is free of burrs or sharp projections that could damage oil seal during installation.
2. Apply a thin coating of sealing compound on the outer edge of the seal and position the seal in the opening so that the seal lip faces toward the inside of the cover.

TIMING CHAIN

OHC 6-230 Engine

Removal

1. Remove timing chain cover.
2. Install tool shown in Fig. 5 on rocker arm cover studs. Install hook of tool in camshaft sprocket and tighten nut to relieve tension on camshaft.
3. Remove fuel pump eccentric from sprocket. Pull forward on sprocket to remove it from camshaft pilot.
4. Release hook of tool and slide sprocket off camshaft.
5. Remove chain tensioner spring to release tension on tensioner blade. Remove blade and spring from lower tensioner mounting stud.

Inspect Chain & Sprockets

Check the chain for excessive wear or stretch. When the chain is installed with the chain tensioner in place, measure the distance between the chain sides at the narrowest point, Fig. 11. If the distance is less than the required minimum as shown the chain must be replaced. If sprockets appear to be excessively worn, replace them also.

Timing Chain Tensioner

This device maintains a constant pressure against the chain to compensate for normal stretch and wear of the chain. Check the contact face of the tensioner blade to make sure the rubber facing material is not worn through. Replace if badly worn. Check the tensioner spring to make sure it is not distorted or elongated.

Install Chain & Sprockets

1. Turn over engine until air starts to blow from No. 1 spark plug port to indicate that No. 1 piston is on the compression stroke.
2. Continue to turn over engine until keyways in crankshaft are in the 12 o'clock position, which will indicate that No. 1 piston is at top dead center, Fig. 12.
3. Temporarily install camshaft sprocket and turn camshaft until nose of No. 1 cam and dowel hole on camshaft are pointing downward at the 6 o'clock position.
4. Remove camshaft sprocket.
5. Install key in crankshaft keyway nearest cylinder block.
6. Install tool shown in Fig. 5.
7. Position sprockets in opposite ends of chain so that keyway in crankshaft sprocket is up and dowel of camshaft is down. Position parts so that copper links of the chain are aligned with timing marks on sprockets.
8. Lift up assembled chain and sprockets and slide crankshaft sprocket on crankshaft so that camshaft is fully seated on camshaft.
9. Engage hook of tool, Fig. 5, on sprocket and tighten nut to tension the chain and pull the mounting hole of the sprocket into alignment with the pilot on end of camshaft.
10. Push sprocket into camshaft pilot so that dowel engages hole in flange on camshaft. This may require slight rotation of crankshaft to secure perfect alignment.
11. Install fuel pump eccentric on camshaft sprocket.
12. Release tension of special tool, Fig. 5, and remove tool from rocker arm cover studs.

"6-226" Engines

For correct valve timing on this engine, install the chain so there are 10 pins between the sprocket timing marks, Fig. 10.

TIMING GEARS

4-Cyl. Engines

The camshaft is driven by a steel gear on the crankshaft and a fibre gear on the camshaft. Lubrication is positive through a jet pressed into the crankcase directly back of the contact point of the gears. When the gears are removed, check both the jet and oil passage to make sure they are clear.

When it becomes necessary to replace the timing gears, due attention must be given to the end play of both shafts and running clearance of the gears.

End play of the crankshaft is controlled by the running clearance between the crankshaft gear and gear thrust plate. The end play is adjusted by shims placed between the thrust plate and the end of the front main bearing. Shims .002 in. thick are available for this adjustment. When the thrust plate or washer is removed, be sure it is reinstalled with the beveled inner edge toward the crankcase.

End play of the camshaft is determined by the running clearance between the camshaft gear and thrust plate. The standard clearance is .003 to .0055 in. which is determined by the thickness of the camshaft gear thrust plate spacer. Should a check indicate not enough clearance, place a thin shim between the thrust plate spacer and the shoulder on the camshaft. Clearance may be reduced by dressing off the spacer slightly. Whenever the spacer is installed, make sure that the beveled inner edge is toward the rear.

End play of both the camshaft and crankshaft can best be measured with a dial indicator.

Standard running clearance between the gears is .000 to .002 in., which should be checked with a dial indicator.

To set the valve timing, install the crankshaft gear followed by the camshaft gear with the camshaft positioned to allow installation with the timing gear marks meshed, Fig. 9.

CAMSHAFT

OHC 6-230 Engine

Removal

1. With cylinder head removed, lift rocker arm guide from cylinder head.
2. Check rocker arms to determine which do not have cam tension against them. *Turn these parallel to camshaft.*
3. Temporarily install camshaft sprocket on camshaft and rotate camshaft to release tension from remaining rocker arms. Turn these parallel to the camshaft also. Continue to do this until all rocker arms are out of engagement with the camshaft.
4. Remove two nuts that attach camshaft retainer to cam bearing support deck and remove retainer.
5. Pull forward on camshaft to remove it from cam bearing support deck.
6. Remove cam bearing support deck from cylinder head.

Inspection

Clean the camshaft thoroughly with a suitable solvent. Make sure all oil passages are free. Check the cams for scoring or wear. The cam face must be perfectly smooth throughout their contact areas. Runout of the camshaft, measured with a dial indicator at the intermediate bearing journals, must not exceed .0005".

Check the camshaft journal diameters with a micrometer. The specified diameters are as follows:

Front	1.9965-1.9975"
No. 2	1.8715-1.8725"
No. 3	1.7465-1.7475"
Rear	1.3715-1.3725"

Check the cam bearing support deck for cracks or distortion. Check the bearing surfaces of the cam deck for visible wear or scoring. Using a telescope gauge and micrometer, check the internal diameters of the cam bearing deck bearings as shown in Fig. 13. The specified diameters are as follows:

Front	1.9995-2.0005"
No. 2	1.8745-1.8755"
No. 3	1.7495-1.7505"
Rear	1.3745-1.3755"

Compare each journal diameter with the corresponding bearing diameter. If the bearings are defective or permit more than .004" running clearance, the cam bearing deck and/or the camshaft must be replaced, Fig. 14.

Installation

1. Install cam bearing support deck on cylinder head. Torque nuts to 15-20 ft-lb.
2. Lubricate bearing with engine oil and carefully slide camshaft into bearing support deck from the front, being careful not to damage bearings in support deck or journals on camshaft.
3. When camshaft is fully seated, install retainer on front of support deck.

4-134 & 6-226 Engines

To remove the camshaft, take off the gear cover as outlined previously and proceed as follows:

1. Remove fuel and oil pumps.
2. Remove camshaft gear and thrust plate.
3. Tie the valve lifters up at their highest point of travel with string wrapped around the adjusting screws

Fig. 13 Checking bearing diameter of cam bearing support deck. 6-230 engine

and attach to manifold studs.

4. Withdraw camshaft from engine and, if necessary, take lifters out from below.
5. Replace the parts in reverse order of removal.
6. When installing the oil pump on 4-cyl. engines, refer to the section covering the oil pump because the pump gear must be properly meshed with the driving gear on the camshaft to correctly couple with the distributor shaft to maintain ignition timing.

PISTONS & RODS, REMOVE

All Engines

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push pistons and rods out of cylinders, using care to prevent rod bolts from contacting and nicking crankshaft journals.

Make sure the rods and pistons are properly numbered so they can be reinstalled in original locations. It is advisable to install caps on rods to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

OHC 6-230 Engine

Assemble the piston to the connecting rod so that when installed in the cylinder the "F" side of the piston will face the front with the oil spurt hole in the rod toward the exhaust (right) side of the engine.

4-Cyl. Engines

As shown in Fig. 15, pistons should be assembled to the connecting rods so that the oil spray hole in the rod faces away from the camshaft side of the engine with the vertical slot in the piston facing the camshaft side.

6-226 Engine

When correctly assembled, the oil spray hole in the rod faces the camshaft side of the engine with the vertical slot in the piston facing away from the camshaft side.

PISTONS, REPLACE

All Engines

Standard size service pistons are high limit or maximum diameter; therefore, they can usually be used with a slight amount of honing to correct slight scoring or excessive clearances in engines having relatively low mileages. Service pistons are also furnished in .005, .010, .015, .020 and .030 in. oversizes.

Before a honing or boring operation is started, measure all new pistons with a micrometer at points exactly 90 degrees away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is very important that refinished cylinder bores are trued up to have not more than .0005 in. out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Fig. 14 Camshaft and cam bearing support deck

Both the piston and cylinder block must be at the same temperature (room temperature of 70 degrees) when the piston is checked for fit in the cylinder bore. Therefore the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10 degrees between the temperature of parts is sufficient to produce a variation of .0005 in.

To check the fit of pistons use a feeler ribbon gauge ¾ in. wide (½" on 6-226 engine) and the thickness listed in the *Piston & Ring Data* chart. Insert the piston upside down in the cylinder bore with rings removed. Locate the feeler 90 degrees from the piston pin hole, between the thrust face of the piston and cylinder wall. Hook the feeler to a spring scale. If the force required to pull the feeler out of the cylinder with the scale is as specified in the chart, the piston fit is correct. If too tight, the cylinder must be honed out until the proper clearance is obtained.

Fig. 15 Assemble pistons and rods as shown. 4 cyl. engines

PISTON RINGS, REPLACE

All Engines

When new piston rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

See the *Piston & Ring Data* chart for ring groove clearances and end gap clearances.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with either end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends with a smooth file.

PISTON PINS, REPLACE

On 6-230 and 6-226 engines the pins are of the full floating type, being retained by snap rings which fit in grooves cut into the piston bosses.

On four cylinder engines, the pins are locked in the rods and are fitted with a clearance of .0001 to .0005 in. which is equivalent to a light thumb push fit with the parts at normal room temperature. No oversize pin is available as it is impossible to ream the connecting rod satisfactorily due to the clamp slot, and also because the piston plating should not be removed from the piston pin bore.

ROD BEARINGS, REPLACE

Insert type bearings consist of two half shells, the upper shell having an oil spray hole which communicates with the oil hole in the rod.

When the shells are placed in the rod and cap the ends extend slightly beyond the parting faces so that when the rod bolts are tightened the shells will be clamped tightly in place to insure positive seating and to prevent turning. *The ends of the shells must never be filed flush with the parting faces of the rod and cap.*

If this type bearing becomes noisy or is worn so that clearance on the crankpin is excessive, a new bearing of proper size must be selected and installed since no provision is made for adjustment. Under no circumstances should the rod or cap be filed to adjust bearing clearance.

Service bearings are furnished in standard sizes and several undersizes, including undersizes for reground crankshafts.

The clearances of connecting rod (and main) bearings may be checked with Plastigage which is available at any auto parts jobber and full instructions for its use are furnished with the envelope in which it is contained.

Lacking Plastigage, however, clearance may be checked with a .002 in. test shim, ¾ in. square. Place the shim between the bearing and shaft journal. Install the cap, tightening the nuts to the recommended torque. A locked bearing or drag when the rod is moved endwise on the crankshaft indicates the clearance is correct providing the rod moves endwise freely without the test shim installed. Do not overlook removing the shim.

The connecting rod nuts are locked with stamped nuts which should not be used when once removed. Install the new nuts with the flat face toward the connecting rod nut. Turn the locking nut finger tight and then tighten it only a half-turn more.

Fig. 16 Crankshaft rear oil seal disassembled. 6-230 engine

MAIN BEARINGS, REPLACE

All Engines

When necessary to remove the crankshaft the engine will have to be removed from the chassis. And since the main bearings on all four-cylinder engines are held in place by dowels, the engine will have to be removed when their replacement becomes necessary.

Main bearings on six-cylinder engines may be removed and installed without removing the engine.

The bearings are made to size and do not require line reaming or adjustment.

When it is necessary to install new bearing shells it is advisable to measure the shaft journals with a micrometer for being out-of-round. If an out-of-round condition exists in excess of the standard running clearance of the bearings (either main or rod) a satisfactory bearing replacement cannot be made and it will be necessary to replace or regrind the crankshaft. Undersize bearings of .010 and .020 in. are available.

Fig. 17 Oil pan seal assembled to rear filler block. 6-230 engine

Before installing the shaft and bearings, use a rifle brush to clean the oil passages thoroughly in both the shaft and crankcase. If possible, blow out the holes with compressed air. Be sure the journals are not nicked or scored and that all parts are thoroughly clean.

After installing the bearings, check the running clearance to be sure it is standard (see *Engine Bearing Data* chart). Use Plastigage or a .002 in. test shim about one inch square. Place the shim between the shaft and bearing and tighten the bearing cap nuts to the recommended torque. The shaft should be locked if the clearance is at the low limit or show a drag if at the high limit when turned, proving that the clearance is correct. Do not overlook removing the test shim.

CRANKSHAFT OIL SEAL

4 Cyl. Engines

The rear main bearing is sealed against external leakage by a lip type neoprene seal with a metal core. The seal has the advantage of being able to be slipped into place without removing the crankshaft.

For easy installation, give the seal a coat of grease. Be careful not to coat the ends of the seal as they have sealing compound applied to them.

OHC 6-230 Engine

The rear end of the crankshaft is sealed against oil leaks by a seal consisting of the parts shown in Fig. 16. The filler block guard is mounted in a recess in the cylinder block.

Before installing a new seal, clean the filler block thoroughly. Remove the oil pan seal and cement used to attach it. Check the dowel pins to make sure they are straight and tight.

To replace the oil pan seal, coat the pan seal groove in the filler block with 3M Super Weatherstrip Adhesive or equivalent for a distance of 2″ from each end, Fig. 17. Also coat the pan seal ends for a distance of 2″.

Insert the nipple of the pan seal into the hole in the bottom of the filler block. Press the ends into engagement with the cemented portion. When in position, the ends of the pan seal should be $\frac{1}{16}$″ below the top of the filler block as shown in Fig. 17. Allow the adhesive to dry before assembly to the engine.

OIL PUMP REPAIRS

4-134 & 6-230 Engines

The oil pump is located externally on the left side of the engine. When necessary to remove the pump, first take off the distributor cap and note the position of the rotor so that the pump may be reinstalled without disturbing the ignition timing.

To install the pump without disturbing the timing, the pump gear must be correctly meshed with the camshaft driving gear to allow engagement of the driving key on the distributor shaft in the pump shaft driving slot without moving the distributor rotor. Assembly can be made only in one position because the slot and

Fig. 18 Oil pump. 4-134 and 6-230 engines

Fig. 19 Water pump. All engines

driving key are machined off center.

To disassemble the pump, Fig. 18, remove the cover and gasket. Hold a hand over the cover opening and, with the pump upside down, turn the shaft until the outer rotor slips out. Drive out the pin securing the drive gear to the shaft. Press the shaft out of the gear and slide the shaft and inner rotor out of the body.

Failure of the pump to operate at full efficiency may usually be traced to excessive end play in the rotor or excessive clearance between the rotors. The clearance between the outer rotor and pump body should also be checked.

End play of the rotors is controlled by the thickness of the cover gasket which is made of special material which can only be slightly compressed. Never use other than a standard factory gasket.

6-226 Engine

The oil pump is of the positive gear type, located at the bottom of the vertical shaft which also drives the distributor.

To disassemble the oil pump, take off the screen float. Drive out the pin which secures the drive gear to the shaft and take off the gear. Remove pump cover and gasket. Position the pump with the drive shaft end up and allow the gears to drop from the pump body. Do not remove the idler gear shaft unless worn or damaged.

Assemble the pump with new parts, using a new gasket. When replacing the upper drive gear, position it on the shaft and use a feeler gauge to measure clearance between gear and end of pump body, allowing a clearance of .002 to .004". When proper clearance has been obtained, drill a $\frac{3}{16}$" pin hole through the drive shaft, install the pin and peen it securely.

WATER PUMP, REPLACE

All Engines

Remove the fan belt and blades, unfasten the pump from the cylnder block and lift it off. On some models, it may be necessary to loosen the radiator core and pull it forward in order to remove the water pump assembly.

WATER PUMP REPAIRS

All Engines

To disassemble the pump, Fig. 19, take out the bearing retaining wire and press the shaft through the impeller and pump body. Remove the seal washer and seal. Place the pump shaft and fan pulley on the press in such a position that the bearing will clear the opening and press the shaft from the pulley.

To reassemble the pump, install the long end of the shaft in the pump body from the front end until the outer end of the bearing is flush with the front end of the pump body.

Dip the seal and seal washer in brake fluid and install in the impeller. Place the impeller on the bed of the press and press the long end of the shaft into the impeller until the end of the shaft is flush with the impeller.

Support the assembly on the impeller end of the shaft and press the fan pulley on the shaft so that the end of the shaft is flush with the face of the fan pulley. Move the shaft in the body so that the grooves in the bearing and pump body line up, then lock in position with the bearing retaining wire.

DISTRIBUTOR, REPLACE

4-134 & 6-230 Engines

The distributor is mounted on the right side of the engine and is operated by a coupling on the oil pump shaft which is driven by a spiral gear on the camshaft.

1. Remove wires from the distributor cap, noting the order in which they are assembled to assure correct reassembly.
2. Remove primary lead from terminal post at side of distributor.
3. Disconnect vacuum tube.
4. Remove distributor cap.
5. Note position of rotor in relation to the distributor housing. Mark housing to facilitate installing and timing.
6. Remove screw holding distributor to crankcase and lift unit from engine.
7. Reinstall in the reverse order of removal and set the timing as outlined below.

"6-226" Engines

To remove the distributor, disconnect the vacuum tube and low tension wire and remove distributor cap. Remove bolt and washer that holds advance arm to adapter and lift out distributor. Install the distributor in the reverse order of removal and set the ignition timing as outlined below.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

Carburetor Section

SERVICE NOTES

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if the fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading on carburetors with automatic choke may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Automatic Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Idle Speed & Mixture Adjustments

The initial setting of the idle mixture screw (or screws) is listed in the carburetor charts. Turn the screw clockwise by hand until it just contacts its seat lightly. Then turn it out the number of turns listed. Start the engine and run it until it reaches normal operating temperature, at which time the choke valve should be wide open with the idle speed screw resting on the lowest step of the fast idle cam. Slowly turn the screw a little at a time until the engine shows a tendency to hesitate and stall. Then turn it to the left until the engine runs smoothly. Continue turning the screw to the left until the fuel mixture is rich and the engine starts to "lope" or "gallop". Finally turn the screw to the right until the engine runs evenly.

On two-barrel carburetors, there is an idle mixture screw for each barrel. When adjusting the idle mixture on two-barrel carburetors, adjust one screw at a time until the engine runs smoothly as directed above. Then adjust the other screw in like manner.

After the idle mixture has been adjusted, it is recommended that a tachometer (engine speed indicator) be used to adjust the slow idle speed to the rpm listed in the *Tune Up Chart*. If a tachometer is not available, adjust the idle speed screw until the engine runs smoothly without racing. If the car has an automatic transmission, place the shift lever in Drive range with hand brake off. Then very slowly increase engine speed until the car begins to creep, then back off slightly until creeping is eliminated.

Choke Thermostat Setting

If necessary to adjust the choke more than two marks from the specified setting, either rich or lean, it indicates that the thermostat spring may be bent or has lost its tension.

Carter Float Settings

When replacing a solid float needle and seat with the new resilient seat, the float setting should be reduced $\frac{1}{32}$" on WCD and WGD carburetors.

CARTER CARBURETOR ADJUSTMENTS

CARTER NOTES

METERING ROD

YF—This adjustment must be checked after adjusting pump and each time the carburetor is reassembled. With throttle valve closed, press down on upper end of diaphragm shaft until diaphragm bottoms in vacuum chamber. Metering rod should contact bottom of metering rod well and metering rod arm should contact lifter link at outer end nearest springs and at supporting lug. Adjust by bending lip of metering rod arm to which metering rod is attached.

WGD and WCD—This adjustment must be made after pump adjustment. With throttle valves closed, press down on vacumeter link until metering rods bottom. With rods held down, revolve metering rod arm until lip contacts vacumeter link. Hold in place and tighten set screw.

CARTER NOTES Continued

Fig. ①—YF float level.

②—With bowl cover held upright, distance between free end of float and bowl cover should be as listed. Adjust by bending stop tabs on float arm.

③—With throttle valve closed, press down on upper end of diaphragm shaft until it reaches bottom. Metering rod arm should now contact pump lifter link at outer end and nearest springs. Adjust by bending pump connector link at lower angle.

④—With choke held wide open, lip of fast idle cam should contact boss on body casting. Adjust by bending at offset portion of choke connector link.

Fig. ⑤—WCD float level.

⑥—With throttle valves closed, distance from top of plunger shaft to top of dust cover boss should be as listed. Adjust by bending throttle connector rod.

⑦—With choke valve closed, tighten fast idle screw on high step of fast idle cam until the clearance listed exists between throttle valve and carburetor bore.

⑧—With throttle wide open, there should be the clearance listed between upper edge of choke valve and inner wall of air horn. Adjust by bending unloader lip on throttle shaft lever.

Fig. ⑨—WGD float level. With solid needle $\frac{9}{32}$", with spring loaded needle $\frac{7}{32}$".

⑩—With throttle valves closed, distance from dust cover boss to top of plunger shaft should be as listed. Adjust by bending throttle connector rod.

⑪—Hold choke valve closed, then close throttle. There should now be the clearance listed between throttle valve and carburetor bore. Adjust by bending choke connector rod.

⑫—With throttle valves wide open, close choke valve as far as possible without forcing. There should now be the clearance listed between upper edge of choke valve and inner wall of air horn. Adjust by bending arm on choke trip lever.

①—Wet Fuel Level: Remove the fuel level check plug from the side of the float bowl. With the engine running at idle speed, the fuel level should be within 1/16" of the bottom line of the check plug port. To adjust the level, loosen the lock screw on the bowl cover and turn the adjusting nut clockwise to lower the fuel level and counterclockwise to raise the level. One-sixth of a turn will change fuel level about 1/16".

②—Pump Override Spring: With throttle held in wide open position and pump operating lever and pin held in fully compressed position, check the clearance between the adjusting nut and the arm of the pump operating lever. The clearance should be as listed.

1963	6-230	2300	1	①	.015②

Clutch Section

AUBURN & ROCKFORD

Both of these clutches are of the single plate dry disc type and both have an 8½" driven plate. The driven plates are built with spring center vibration neutralizers and have two flexible facings which provide smooth engagement of the engine power. Both clutches have approximately the same torque capacity and total plate pressure and use the same driven plate and release bearing.

Clutch Pedal, Adjust

As the clutch facings wear the free pedal travel diminishes. When sufficient wear occurs to cause the pedal to rest against the toe board it is necessary to adjust the free travel.

The free pedal travel, which should be 1½", is adjusted by lengthening or shortening the clutch control lever cable. Loosen the clutch control lever cable adjusting yoke lock nut. Unscrew the cable with a wrench and tighten the lock nut.

Clutch Assembly, Replace

To remove the clutch, follow the procedure outlined in the transmission section for the removal of the transmission or transmission and transfer case from the vehicle.

Note that labor will be saved when removing the clutch from four-wheel drive models equipped with a transfer case if the engine is removed from the chassis without the bell housing.

Remove the transmission and bell housing from vehicles not equipped with a transfer case. Then remove the clutch from the flywheel.

If the same clutch is to be reinstalled, mark both the pressure plate and flywheel so that the assembly may be installed in the same position.

Install the clutch in the reverse order of its removal and adjust the clutch control cable to establish the proper free pedal travel.

Transmission & Transfer Case Section

TRANSMISSION, REPLACE

Four Wheel Drive

1. Remove front and rear propeller shafts.
2. If vehicle is equipped with a power take-off, disconnect transfer case end of power take-off drive shaft.
3. Disconnect speedometer cable at transfer case.
4. Disconnect brake cable.
5. Support transmission and engine with jacks.
6. Remove nuts holding rear mounting to frame crossmember.
7. Remove transfer case snubbing rubber bolt nut at crossmember.
8. Remove shift lever or remote control rods.
9. Disconnect clutch release cable at bell crank at yoke end.
10. Remove floor board inspection plate.
11. Remove transfer case shift lever pivot pin screw.
12. Remove transfer case shift lever pivot pin and remove levers. If vehicle is equipped with power take-off, remove shift lever plate screws and lift out lever.
13. Remove frame center crossmember.
14. Remove bolts holding transmission to bell housing.
15. Force transmission to right to disengage clutch control lever tube ball joint.
16. Lower jacks under engine and transmission and slide transmission and transfer case toward rear of vehicle until clutch shaft clears bell housing.

Separate Transmission From Transfer Case

1. Drain lubricant from both units.
2. Remove five screws from cover on rear face of transfer case (if equipped with power take-off, remove power take-off shift housing).
3. Remove transfer case main drive gear from rear end of transmission mainshaft.
4. Remove shift tower from transmission.
5. In the absence of a transmission mainshaft retaining plate, loop a piece of wire around the mainshaft just back of the second speed gear, twist the wire and attach one end to right hand front cover screw and the other end to left hand cover screw.
6. Draw wire tightly to prevent mainshaft from pulling out of transmission case when transfer case is removed.
7. Separate the two housings, using care to see that the transmission mainshaft bearing, which bears in both housings, remains in the transmission case.
8. Reverse the removal procedure to attach the transmission to the transfer case and install the assembly in the vehicle.

Two-Wheel Drive

The following outline covers removal of transmission and overdrive. If not so equipped, disregard operations pertaining to overdrive.

1. Disconnect remote control rods at transmission.
2. Disconnect two wires from overdrive solenoid. *Tag wires and terminals to assure correct assembly.*
3. Disconnect two wires at overdrive rail switch. *Tag wires and terminals to assure correct assembly.*
4. Disconnect front universal joint, and speedometer cable at transmission. Have available an ordinary cork of correct size to close cable opening to prevent leakage of lubricant.
5. Disconnect overdrive control cable and conduit.
6. Remove rubber mounted saddle support at rear end of overdrive. Use care not to lose spacers. Remove overdrive.
7. Place jack under flywheel bell housing and raise it to support weight of housing.
8. Remove frame cross member with rubber insulators attached.
9. Place jack under engine to support engine when transmission is removed.
10. Thread out four screws attaching transmission to bell housing as far as possible and yet support weight of transmission. Pull transmission back to bolt heads which will provide approximately ¾" opening between the two housings and at the same time relieve pressure on clutch release fork in bell housing.
11. Use a long screwdriver through opening in side of bell housing to pry clutch release fork from engagement with clutch release bearing carrier.
12. Complete removal of four transmission attaching screws and pull transmission back until clutch shaft clears bell housing and remove the assembly with release bearing carrier attached.

Fig. 1 Transmission. All 4-wheel drive models

Fig. 2 Transmission. Two-wheel drive models

TRANSMISSION REPAIRS

Four Wheel Drive, Fig. 1

1. Drain lubricant from case and clean case with a suitable solvent.
2. If transfer case is attached, remove its rear cover.
3. If equipped with a power take-off, remove the shift unit which replaces the cover.
4. Remove transfer case main drive gear.
5. Remove transmission cover.
6. Loop a piece of wire around mainshaft directly back of mainshaft second speed gear. Twist wire and attach one end to right hand front cover screw and other end to left front screw. Draw wire tightly to prevent mainshaft from pulling out of transmission case when transfer case is removed. Should mainshaft come out, synchronizer parts will drop into bottom of case.
7. Support transfer case and with a rawhide mallet or brass drift and hammer, tap lightly on end of transmission mainshaft to separate the two units. The transmission mainshaft bearing should slide out of transfer case and remain in transmission.
8. Remove drive gear bearing retainer.
9. Remove lock plate and drive countershaft out through rear.
10. Remove mainshaft rear bearing adapter.
11. Remove mainshaft and gear assembly through transfer case opening.
12. Remove countershaft gearset and thrust washers, noting position of washers.
13. Drive reverse idler shaft out rearward and lift out gear.

Assembly Notes

Reverse the order of the above procedure to assemble the transmission, being sure to observe the following precautions:

The countershaft gearset should have from .012″ to .018″ end play when assembled in the case. This clearance is obtained by selective thickness of the rear steel thrust washer, which is available in two thicknesses. Assemble the larger bronze washer at the front of the case with the lip entered in the slot in the case. The bronze faced steel washer goes next to the gear at the rear end, and the steel washer next to the case. Use a loading sleeve to assemble the countershaft roller bearings.

Two Wheel Drive, Fig. 2

1. Remove cover, front flange and snap rings from pinion bearing.
2. Use puller to remove pinion bearing, using a suitable synchronizer ring protector to take up the thrust and prevent possible damage to the synchronizer.
3. Pull off the companion flange, remove the rear bearing retainer and oil seal, and slide the speedometer drive gear off the shaft.
4. Mark the synchronizer blocker rings, gear and sleeve so that these parts may be reassembled in their original position.
5. Raise the drive pinion over the countershaft gear, pull the mainshaft and bearing rearward and remove the drive gear from the case.
6. Cock the mainshaft to the side as far as possible, disengage and remove the shift forks.
7. Release the mainshaft front snap ring. Grasp the mainshaft parts and slide the shaft through these parts and out through the rear.
8. Remove the lock plate and drive the countershaft out rearward.
9. Lift out the cluster gear and washers, noting the position of these parts.
10. Drive out the shaft and lift out the reverse idler gear.
11. Remove the shift shaft locating pins and take out the shift levers and shafts and oil seals.
12. Assembly may be made in the reverse order, being sure to use new gaskets and oil seals.

TRANSFER CASE

Four Wheel Drive, Fig. 3

In removing the transfer case, follow the procedure outlined under transmission removal. Then dismantle the case as follows:

1. Remove propeller shaft flange, brake assembly and linkage.
2. Remove lower cover.
3. Remove lock plate.
4. Drive intermediate shaft to rear of

Fig. 3 Transfer case for four-wheel drive models

case, being careful not to lose thrust washers.

5. Remove intermediate gear, thrust washers and roller bearings through bottom of case.
6. Shift front wheel drive to engaged position (shaft forward) and remove poppet plugs, springs and balls on both sides of output bearing cap.
7. Remove output bearing cap together with the universal joint end yoke, clutch shaft, bearing, clutch gear, fork and shift rod. Use care not to lose the interlock.
8. Remove output shaft snap ring and thrust washer.
9. Use a rawhide mallet to drive against the front end of the mainshaft to start the rear bearing from the case. As the shaft is removed, the gears will remain in the case and can be taken out through the bottom, also the snap ring and thrust washer.
10. Remove set screw in sliding gear shift fork and take out the shift rod.
11. Disassemble the front and rear bearing caps as required.

Assembly Notes

Reverse the order of the above procedure to assemble the transfer case. But when rear bearing cap assembly is installed, check the end movement of the mainshaft which determines the adjustment of the tapered roller bearings. For correct bearing adjustment, the shaft should have from .004″ to .008″ end play. Adjustment is made by selective shim installation between the cap and case. Shims .003″, .010″ and .031″ thicknesses are available for this adjustment. Do not install the rear cap oil seal until the bearings are properly adjusted.

"Live" Front & Rear Axle Section

Fig. 1 Spicer single reduction axle with one-piece banjo type housing

SPICER

One-Piece Housing Type, Fig. 1

This rear axle, is of the semi-floating, hotchkiss drive type. The drive pinion is the over-hung type, mounted on pre-loaded taper roller bearings. Sealing of the pinion shaft is accomplished at the front end by a spring-loaded leather seal bearing on the companion flange, which is splined and secured to the pinion shaft by a nut.

Axle Shaft, Remove

To remove an axle shaft, jack up the wheel and pull off the hub and brake drum. Block the brake pedal in such a manner that it cannot be depressed. Disconnect the hydraulic brake line from the wheel cylinder. Remove the mounting screws and take off the outer oil seal, shims and brake support. The shaft and bearing may then be pulled out of the housing. The inner oil seal may be removed at this time.

Axle Shaft, Install

Replace the shaft and bearings in the reverse order. If the old parts are replaced and the shims have not been disturbed, the end play should be correct when the parts are assembled. However, if a new axle shaft, bearing, differential carrier or housing has been installed, it will be necessary to check the end play.

Axle Shaft End Play, Adjust

Axle shaft end play can be checked when all parts have been replaced except the wheel and hub. To make the check, rap each axle shaft after the nuts are tight to be sure the bearing cups are seated. Then mount a dial indicator on the axle housing with its contact button touching the end of the shaft. Work the shaft in and out by hand and note the reading on the indicator. If an adjustment is necessary, remove the oil seal and brake support and add or remove shims as required to bring the end play to .001" to .005".

When making this adjustment, an equal thickness of shims should be removed or added on each side of the axle housing to maintain the central position of the axle shafts.

Fig. 2 Prying differential from housing

Rear Axle Assembly, Replace

Inasmuch as the axle tubes are pressed into the differential carrier to form a one-piece housing, the rear axle assembly must be removed from the chassis when it becomes necessary to overhaul the unit.

1. Raise vehicle from floor and support with stand jacks under frame side rails.
2. Remove rear wheels.
3. Split rear universal joint.
4. Disconnect parking brake cable (if equipped) from operating lever and from brake backing plates.
5. Disconnect hydraulic brake line connection at rear axle housing.
6. Loosen and move shock absorbers out of the way.
7. While supporting axle housing with hydraulic jack, remove spring clips and lower axle assembly to the floor.
8. Reverse the foregoing procedure to

Fig. 3 Adjustments on Spicer axle

install the rear axle assembly, being sure to bleed the brake system when the installation is completed.

Differential Carrier, Disassemble

1. Remove axle shafts as outlined previously. Axle shafts may be pulled out only far enough to clear differential side gears.
2. Drain lubricant and remove rear cover.
3. Make sure differential side bearing caps and axle housing are marked, then remove the side bearing caps.
4. Pry differential from housing, Fig. 2.
5. Remove side bearing cups.
6. Pull off side bearings and adjusting shims, tagging the shims for identification on reassembly.
7. Unfasten ring gear from case.
8. Drive out differential pinion shaft pin and pull out the shaft, pinions and side gears.
9. Hold companion flange from turning and remove flange nut.
10. Pull flange from pinion shaft.
11. Remove pinion from carrier by tapping on front end with soft hammer.
12. Remove pinion shaft bearing oil seal and bearings from carrier, keeping separate the shim pack at each bearing.

Pinion & Bearings, Replace

If the original ring gear and pinion are being used in the original carrier, use the original shim packs at each bearing, Fig. 3. If a new pinion or differential carrier is installed, note the markings on the end of the pinion gear and on the differential carrier to obtain the correct thickness of shimming to be used with these parts from your supplier. The shims behind the rear bearing establishes the correct pinion depth.

1. Press the rear pinion bearing cup in the housing with the proper thickness of shims. Press the rear pinion bearing on the shaft.
2. Install the front bearing cup and shims, and front bearing.
3. Install the companion flange and, while holding the flange from turning, tighten the nut to a torque load of 200-220 lb. ft.
4. Check the pinion bearing pre-load with a spring scale and heavy cord wrapped around the companion flange. Pull on the spring scale. The torque required to rotate the pinion is 10-30 inch lbs. If not within these limits, add or remove shims from behind the front bearing to obtain the proper pre-load.
5. Remove the companion flange and install a new oil seal (well soaked). Reinstall the companion flange and tighten the nut.

Ring Gear, Replace

1. Install guide pins in every other hole in the ring gear. These pins can be made from 1½" long capscrews with heads cut off and ends slotted.
2. Make sure back face of ring gear and face of case are free of dirt and burrs and slip gear over pilot diameter of case.
3. Install every other ring gear bolt. Draw them up evenly and snugly so ring gear face is flush with face of case.
4. Remove guide pins and install remaining bolts.

Differential Carrier, Assemble

The differential bearings are adjusted by shims, Fig. 3. These shims also establish the ring gear position with the pinion. Therefore, backlash must be checked whenever a bearing adjustment is made.

The correct bearing adjustment is one which will provide a .008" pinch fit when the differential unit is assembled into the carrier. To make the adjustment, install the bearing cones without shims and place the assembly in the housing with the bearing cups. Force the unit to one side and check the clearance between the bearing cup and differential case with a feeler gauge, Fig. 4. When the clearance is determined, select shims of this amount plus .008" extra to establish the proper pre-load.

Remove the differential bearings again and divide the shims into two packs of equal thickness and install on each side and replace the bearings. Reinstall the unit in the carrier. This operation is made easier by cocking the bearing cups slightly when the differential is placed in the housing and then tapping them lightly with a mallet, Fig. 5. However, when installing the differential in the housing, be sure the ring gear teeth mesh with the pinion teeth before tapping the bearings in place.

After the bearing cups are firmly in place, install the bearing caps. The bearing caps and gasket surface of the housing are marked with a horizontal numeral and on the other side by a vertical numeral. The position of the numerals should correspond when reinstalling the bearing caps.

Ring Gear & Pinion Blacklash, Adjust

Mount a backlash gauge indicator on

Fig. 4 Checking clearance between bearing cup and differential case. Spicer axle

Fig. 5 Installing differential bearing cups. Spicer axle

Fig. 6 Method of correcting backlash between ring gear and pinion

Fig. 7 Short heel contact. Move ring gear toward pinion

Fig. 8 Short toe contact. Move ring gear away from pinion

the carrier and start checking for the correct backlash between the ring gear and pinion. If the backlash is not within the limits of .004" to .009", it will be necessary to change the arrangement of the shims back of the bearings. Make corrections in backlash according to Fig. 6, bearing in mind that shims removed from one side must be installed on the opposite side so that the total shim thickness of the right and left side will remain unchanged, and the bearing adjustment undisturbed.

Gear Tooth Contact Pattern

Allowable variations in the carrier or drive pinion may cause the pinion to be too far in or out even when shimmed properly. Thus, the tooth contact must be tested and corrected as necessary or the gears may be noisy.

Paint the ring gear teeth with a light coating of red lead, white lead or prussian blue. Revolve the gears and observe the contact, referring to Figs. 7 to 11.

SPLIT HOUSING REAR AXLE

Remove & Disassemble, Fig. 12

It is necessary to divide the axle housing at the center to inspect or remove the differential. The differential may be removed without removing the pinion shaft. The pinion shaft and bearing assembly may be removed without dividing the axle housing.

Drain the lubricant from the housing. Raise the vehicle to remove the weight from the rear wheels and axle. Remove the spring clips which attach the left side of the axle housing to the spring. Place a jack under the right housing next to the differential to support the weight when the left housing is removed. Remove the screws connecting the two housing halves. Skid the left housing to the left to separate the housing halves, pulling the left axle shaft from the differential splines. The differential as an assembly may then be removed from the right housing.

The ring gear is riveted to the differential case. However, the differential gears and thrust washers may be installed without removing the ring gear by dividing the differential case.

The differential gears and thrust washers are supplied only as matched sets, and only the spider is supplied separately. Therefore, if any of the differential parts (except spider) must be replaced, the complete set must be installed.

Drive Pinion, Disassemble

The pinion shaft and bearing assembly may be removed without disturbing the differential assembly or dividing the axle housing.

To remove the pinion and bearing assembly, take off the pinion shaft cover with the oil seal. Use a puller to remove the pinion shaft assembly.

The pinion shaft is mounted on two tapered roller bearings with a double cup made as a single piece. To remove the bearings, remove the lock nut, washer and adjusting nut. The front bearing cone and double bearing cup may be easily removed as the cone is a slip fit on the shaft. Use a suitable puller to remove the rear cone. The pinion shaft pilot (straddle) bearing is mounted in the axle housing and is positioned by a retainer plate. Two rivets hold the plate against the housing. To remove the pilot bearing, first drive out the rivets from the front side of the axle, remove the retainer plate and drive the bearing from the housing.

The axle parts are precision machined and no adjustment of ring gear and pinion mesh is provided. The ring gear and pinion is supplied only in matched sets and the pinion shaft pilot bearing race is supplied mounted on the shaft pilot.

Pinion & Bearings, Assemble

1. Install pilot bearing retainer and drive bearing in place.
2. If necessary, press pilot bearing inner cup onto pinion shaft and install snap ring.
3. Press rear pinion shaft bearing firmly against pinion shoulder.
4. Position cup over rear bearing.
5. Install front bearing.
6. Install washer, adjusting nut, locking washer and lock nut.

Fig. 9 Contact too low and narrow. Pinion should be moved away from center of axle

Fig. 10 Contact too high and narrow. Pinion should be moved toward center of axle

Fig. 11 Correct tooth contact. Gears making contact as shown give best results for quiet operation and long life

7. Set adjusting nut so that the bearings are preloaded 12-18 inch lbs.

This preload may be checked with a spring scale attached to the pinion shaft and by rotating the shaft by pulling on the scale the preload may be determined. This preload is necessary for satisfactory operation because these bearings carry the thrust as well as radial load. Guard against overtightening, however, as heating and bearing failure might result.

Fig. 12 Timken split housing type axle with two-piece differential case

Final Assembly

Install the pinion assembly in the housing, being sure the pilot bearing race enters the pilot bearing in the housing. Check the oil seal in the pinion shaft cover and drive a new seal in place, if necessary. Position new gaskets on the bearing spacer (retainer) with the oil drain hole in alignment with the opening in the housing, and install the cover.

Install the differential assembly and fasten the housing halves. When assembly is completed, check the backlash between the ring gear and pinion which must be between .004" and .018".

Installation in Vehicle

To install the axle under the vehicle, have the end of the vehicle securely supported with a chain hoist or a support under the frame just ahead of the rear springs. Place the axle assembly in position and raise it so the spring clips and front spring bolts may be installed. Connect the brake line hose at the frame, install lock clip and attach brake line. Connect the propeller shaft at the rear universal joint. The wheels may then be installed and the vehicle lowered to the floor. Bleed the brakes to remove any air from the lines.

"LIVE" FRONT AXLE

Four-Wheel Drive Models, Fig. 13

The front axle on these models is a live driving unit with hypoid driving gears and spherical steering knuckles mounted on pivot pins which ride on tapered roller bearings for ease of steering. The drive is of the full-floating type through axle shafts built integrally with constant velocity universal joints which revolve in the steering knuckles.

Front Axle Service

The differential is mounted in a housing similar to that used in the rear axle except that the pinion shaft faces toward the rear instead of to the front and to the right of the center of the axle. This design allows the placing of the front propeller shaft along the right side of the engine oil pan to avoid reducing road clearance under the engine.

The axle is of the full floating type and the axle shafts can be removed without dismantling the steering knuckle housing.

Overhaul of this axle unit is the same as the rear axle.

Service Note (Axle Shafts)

A change in design of the front axle on four-wheel drive vehicles was placed

Fig. 14 Bendix type axle shaft and universal joint

Fig. 13 "Live" front axle. Four-wheel drive models

in production effective with the following serial numbers:

No. 37549 on CJ-3A
No. 44070 on 4WD
No. 14284 on 4x463

In the new design the front axle shaft outer splined end floats in the wheel driving flange and is not retained by a nut and lockwasher as originally used. With this construction it is no longer necessary to install shims between the driving flange and wheel hub to provide the correct end float of the axle shaft universal joint.

The new construction, when using the Bendix type axle shaft, is shown in Fig. 14. Note that the end float of the Bendix type joint is predetermined in manufacturer by the position and flange thickness of the bushing and thrust washer. These parts are so positioned and of the correct thickness to provide .088" maximum end float of the universal joint to operate at the centerline of the spindle pivot pins. With the correct joint end float controlled by the bushing flange and thrust washer, it is no longer necessary to install shims between the driving flange and wheel hub, a gasket only being used.

The new type Bendix axle shaft and universal joint may be readily installed in an old type axle by installing the new type flanged bushing. When this is done, discard the shims previously installed between the flange and hub, installing a gasket only. The flanged bushing requires no reaming and is so designed

Fig. 15 Rzeppa type axle shaft and universal joint

Fig. 16 Front steering knuckle with Bendix axle shaft and universal joint (early type)

that when it is pressed into the spindle it will be compressed to provide correct running clearance. Coat the inner surface of the bushing with chassis grease before installing the spindle.

The axle construction is similar for installation of the Rzeppa joint, Fig. 15. The thrust washer is not necessary although it is installed in all axles to allow installation of the Bendix type shaft if so desired. As the thrust washer is not effective, a snap ring is installed at the outer end of the shaft to control end float.

Steering Knuckle Pivot Pins, Fig. 16

When reinstalling a steering knuckle, sufficient shims must be installed under the bearing caps so the proper tension will be obtained on the bearings. The shims are available in thicknesses of .003", .005", .010" and .030".

Install one each of the shims over the studs on the steering knuckle at the top and bottom. Install the bearing caps, lock washers and nuts and tighten securely. Check the tension of the bearings by hooking a spring scale in the hole in the arm for the tie rod socket. The load should be 6-9 lbs. without the oil seal in position and is secured by adding or removing shims as required. Make sure there are the same thickness of shims between the upper cap and the knuckle as between the lower cap and knuckle.

Service Note (Lower Shims)

On models CJ-3A, 473-4WD and 4x473, .058" was added to the bottom face of the king pin boss on the steering knuckles. This eliminated the shims for the lower kingpin bearing and the adjustment of the bearing is now made by shims at the top only.

Steering Gear Section

Fig. 1 Ross cam and lever steering gear with twin studs

ROSS CAM & LEVER STEERING GEAR

This steering gear, Fig. 1, is the cam and twin lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove, causing the lever arm to rotate the lever shaft. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and the cam where most of the steering action occurs.

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the lock nut adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are .002", .003" and .010" thickness.
4. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim. If necessary, remove or replace shims until the adjustment is correct.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then, starting from this point, count the number of turns required to reach end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but a slight drag should be felt in the mid-position only.
3. After proper adjustment is secured, tighten the lock nut and give the gear a final check for binding.

Steering Gear, Replace

It is necessary to pass the steering gear down through the floor pan. The procedure is as follows:

1. Remove left front fender on CJ-2A and CJ-3A.
2. Disconnect remote control rods from levers on steering column if equipped with steering post shift.
3. Remove horn button and steering wheel.
4. Remove steering post bracket at instrument panel.
5. Remove steering post hand lever.
6. Remove exhaust pipe from manifold.
7. Remove steering column cover plate on toe board.
8. Remove two screws attaching remote control housing to steering column.
9. Remove horn wire contact brush (CJ-2A) or disconnect horn wire.
10. Remove remote control gearshift assembly down through floor pan.
11. Remove pitman arm from steering gear.
12. Unfasten steering gear from frame and bring it down through the floor pan and over the outside of the frame side rail.

①—Single spring used.
②—Intake 30°, exhaust 45°.
③—Long 2400–2500, short 1800–1850.
④—With sodium-cooled exhaust valves intake .011C. exhaust .020C.
⑤—Intake valve spring.
⑥—Exhaust valve spring.
⑦—Cap screws with former 3/16″ hole drilled through to be torqued 950–1000. Present hole (3/16 top—1/8 bottom) torque to 1150–1200.
⑧—Engines with degree marks instead of stamped marks on flywheel have timing data noted on engine.
⑨—Valve clearances stamped on WAUKESHA engine name plate for cold settings only.
⑩—1L–4R–4L–2L–3R–3L–2R–1R.
